(Received ?, revised ?, accepted ?. - To be entered by editorial office)

We perform a local stability analysis of rotational flows in the presence of a constant vertical magnetic field and an azimuthal magnetic field with a general radial dependence characterized by an appropriate magnetic Rossby number. Employing the short-wavelength approximation we develop a unified framework for the investigation of the standard, the helical, and the azimuthal version of the magnetorotational instability, as well as of current-driven kink-type instabilities. Considering the viscous and resistive case, our main focus is on the case of small magnetic Prandtl numbers which applies, e.g., to liquid metal experiments but also to the colder parts of accretion disks. We show in particular that the inductionless versions of MRI that were previously thought to be restricted to comparably steep rotation profiles extend well to the Keplerian case if only the azimuthal field slightly deviates from its field-free profile.

Key words:

1. Introduction

The interaction of rotational flows and magnetic fields is of fundamental importance for many geo- and astrophysical problems (Rüdiger, Hollerbach, Kitchatinov 2013). On one hand, rotating cosmic bodies, such as planets, stars, and galaxies are known to generate magnetic fields by means of the hydromagnetic dynamo effect. Magnetic fields, in turn, can destabilize rotating flows that would be otherwise hydrodynamically stable. This effect is particularly important for accretion disks around black holes and protostars, where it allows for the tremendous enhancement of outward directed angular momentum transport that is necessary to explain the typical mass flow rates onto the respective central objects. Although this magnetorotational instability (MRI), as we call it now, had been discovered already in 1959-60 by Velikhov (1959) and Chandrasekhar (1960), it was left to Balbus & Hawley (1991) to point out its relevance for astrophysical accretion processes. Their seminal paper has inspired many investigations related to the action of MRI in active galactic nuclei (Krolik 1998), X-ray binaries (Done, Gierliński & Kubota 2007), protoplanetary disks (Armitage 2011), and even planetary cores (Petitdemange, Dormy & Balbus 2008).

An interesting question concerns the non-trivial interplay of the hydromagnetic dynamo effect and magnetically triggered flow instabilities. For a long time, dynamo research had been focussed on how a pre-given flow can produce a magnetic field and,
to a lesser extent, on how the self-excitation process saturates when the magnetic field becomes strong enough to act against the source of its own generation. Similarly, most of the early MRI studies have assumed some pre-given magnetic field, e.g. a purely axial or a purely azimuthal field, to assess its capability for triggering instabilities and turbulent angular momentum transport in the flow. Nowadays, however, we witness an increasing interest in treating the dynamo effect and instabilities in magnetized flows in a more self-consistent manner. Combining both processes one can ask for the existence of \textit{“self-creating dynamos”} \cite{Fuchs99}, i.e. dynamos whose magnetic field triggers, at least partly, the flow structures that are responsible for its self-excitation.

A paradigm of such an essentially non-linear dynamo problem is the case of an accretion disk without any externally applied axial magnetic field. In this case the magnetic field can only be produced in the disk itself, very likely by a periodic MRI dynamo process \cite{Hera11} or some sort of an \(\alpha-\Omega\) dynamo \cite{Brandenburg95}, the \(\alpha\) part of which relies on the turbulent flow structure arising due to the MRI. Such a closed loop of magnetic field self-excitation and MRI has attracted much attention in the past, though with many unsolved questions concerning numerical convergence \cite{Fromang07}, the influence of disk stratification \cite{Shi10}, and the role of boundary conditions for the magnetic field \cite{Kapyla11}.

In problems of that kind, a key role is played by the so-called magnetic Prandtl number \(Pm = \nu/\eta\), i.e. the ratio of the viscosity \(\nu\) of the fluid to its magnetic diffusivity \(\eta = 1/\mu \sigma\) (with \(\mu\) denoting the magnetic permeability and \(\sigma\) the conductivity). While closed-loop MRI-dynamo processes can easily be shown to work for \(Pm \propto 1\), its functioning for small values of \(Pm\), as it is typical for the outer parts of accretion disks around black holes, and for protoplanetary disks, is far from being settled. While \cite{Lesur07} have argued for a power-law decline of the turbulent transport with decreasing \(Pm\), other authors find indications for some critical \(Rm\) in the order of \(10^3\ldots10^4\) beyond which the MRI-dynamo loop seems to work \cite{Fleming00, Oishi11}.

Another paradigm of the interplay of self-excitation and magnetically triggered instabilities is the so-called Tayler-Spruit dynamo as proposed by \cite{Spruit02}. In this particular (and controversially discussed) model of stellar magnetic field generation, the \(\Omega\) part of the dynamo process (to produce toroidal field from poloidal field) is played, as usual, by the differential rotation, while the \(\alpha\) part (to produce poloidal from toroidal field) is taken over by the flow structure arising from the kink-type Tayler instability \cite{Tayler73} that sets in when the toroidal field acquires a critical strength to overcome stable stratification.

At small values of \(Pm\), both dynamo and MRI related problems are very hard to treat numerically. This has to do with the fact that both effects rely on induction effects which require some finite magnetic Reynolds number. This number is the ratio of magnetic field production by the velocity to magnetic field dissipation due to Joule heating. For a fluid flow with typical size \(L\) and typical velocity \(V\) it can be expressed as \(Rm = \mu_0 \sigma LV\). The numerical difficulty for small \(Pm\) problems arises then from the relation that the hydrodynamic Reynolds number, i.e. \(Re = Pm^{-1} Rm\), becomes very large, so that extremely fine structures have to be resolved. Furthermore, for MRI problems it is additionally necessary that the magnetic Lundquist number, which is simply a magnetic Reynolds number based on the Alfvén velocity \(v_A\), i.e. \(S = \mu_0 \sigma L v_A\), must also be in the order of 1.

A complementary way to study the interaction of rotating flows and magnetic field at small \(Pm\) and comparably large \(Rm\) is by means of liquid metal experiments. As for the dynamo problem, quite a number of experiments have been carried out \cite{Stefani11}.
Instabilities in magnetized rotational flows

Up to present, magnetic field self-excitation has been attained in the liquid sodium experiments in Riga (Gailitis et al. 2000), Karlsruhe (Müller & Stieglitz 2000), and Cadarache (Monchaux et al. 2007). Closely related to these dynamo experiments, some groups have also attempted to explore the standard version of MRI (SMRI), which corresponds to the case that a purely vertical magnetic field is being applied to the flow (Sisan et al. 2004; Nornberg et al. 2010). Recently, the current-driven, kink-type Tayler instability was identified in a liquid metal experiment (Seilmayer et al. 2012), the findings of which were numerically confirmed in the framework of an integro-differential equation approach by Weber et al. (2013).

With view on the peculiarities to do numerics, and experiments, on the standard version of MRI at low Pm, it came as a big surprise when Hollerbach & Rüdiger (2005) showed that the simultaneous application of an axial and an azimuthal magnetic field can change completely the parameter scaling for the onset of MRI. For $B_φ/B_z \propto 1$, the helical MRI (HMRI), as we call it now, was shown to work even in the inductionless limit (Priede 2011; Kirillov & Stefani 2011), $Pm = 0$, and to be governed by the Reynolds number $Re = RmPm^{−1}$ and the Hartmann number $Ha = SPm^{−1/2}$, quite in contrast to standard MRI (SMRI) that was known to be governed by $Rm$ and $S$ (Ji et al. 2001).

Very soon, however, the enthusiasm about this new inductionless version of MRI cooled down when Liu et al. (2006) showed that HMRI would only work for comparably steep rotation profiles. Using a short-wavelength approximation, they were able to identify a minimum steepness of the rotation profile $Ω(R)$, expressed by the Rossby number $Ro := R(2Ω)^{−1}∂Ω/∂R < ROLL = 2(1−√2) ≈ −0.828$. This limit, which we will call the lower Liu limit (LLL) in the following, implies that the inductionless HMRI in the case when $B_φ(R) \propto 1/R$ does not extend to the Keplerian case, characterized by $Ro_{Kep} = −3/4$. Interestingly, Liu et al. (2006) found also a second threshold of the Rossby number, which we call the upper Liu limit (ULL), at $Roull = 2(1+√2) ≈ +4.828$. This second limit, which predicts a magnetic destabilization of extremely stable flows with strongly increasing angular frequency, has attained nearly no attention up to present, but will play an important role in the present paper.

As for the general relation between HMRI and SMRI, two apparently contradicting observations have to be mentioned. On one hand, the numerical results of Hollerbach & Rüdiger (2005) had clearly demonstrated a continuous and monotonic transition between HMRI and SMRI. On the other hand, HMRI was identified by Liu et al. (2006) as a weakly destabilized inertial oscillation, quite in contrast to the SMRI which represents a destabilized slow magneto-Coriolis wave. Only recently, this paradox was resolved by showing that the transition involves a spectral exceptional point at which the inertial wave branch coalesces with the branch of the slow magneto-Coriolis wave (Kirillov & Stefani 2010).

The significance of the LLL, together with a variety of further predicted parameter dependencies, was experimentally confirmed in the PROMISE facility, a Taylor-Couette cell working with a low Pm liquid metal (Stefani et al. 2006, 2007, 2009). Present experimental work at the same device (Seilmayer et al. 2013) aims at the characterization of the azimuthal MRI (AMRI), a non-axisymmetric “relative” of the axisymmetric HMRI, which is expected to dominate at large ratios of $B_φ$ to $B_z$ (Hollerbach et al. 2010). However, AMRI as well as inductionless MRI modes with any other azimuthal wavenumber (which may be relevant at small values of $B_φ/B_z$), seem also to be constrained by the LLL as recently shown in a unified treatment of all inductionless versions of MRI by Kirillov et al. (2012).

Actually, it is this apparent failure of HMRI, and AMRI, to apply to Keplerian profiles that has prevented a wider acceptance of those inductionless forms of MRI in the astro-
physically sensible modification would allow HMRI to extend to Keplerian flows?

Quite early, the validity of the LLL for $B_\phi(R) \propto 1/R$ had been questioned by Rüdiger & Hollerbach (2007). For the convective instability, they found an extension of the LLL to the Keplerian value in global simulations when at least one of the radial boundary conditions was assumed electrically conducting. Later, though, by extending the study to the absolute instability for the travelling HMRI waves, the LLL was vindicated even for such modified electrical boundary conditions by Friedel (2011). Kirillov & Stefani (2011) made a second attempt by investigating HMRI for non-zero, but low $S$. For $B_\phi(R) \propto 1/R$ it was found that the essential HMRI mode extends from $S = 0$ only to a value $S \approx 0.618$, and allows for a maximum Rossby number of $\text{Ro} \approx -0.802$ which is indeed slightly above the LLL, yet below the Keplerian value. A third possibility may arise when considering that saturation of MRI could lead to modified flow structures with parts of steeper shear, sandwiched with parts of shallower shear (Umurhan 2010).

A recent letter (Kirillov & Stefani 2013), has suggested another way of extending the range of applicability of the inductionless versions of MRI to Keplerian profiles, and beyond. Rather than relying on modified electrical boundary conditions, or on locally steepened $\Omega(R)$ profiles, we have evaluated $B_\phi(R)$ profiles that are shallower than $1/R$.

The main physical idea behind this attempt is the following: assume that in some low-$P_m$ regions, characterized by $S << 1$ so that standard MRI is reliably suppressed, $R_m$ is still sufficiently large for inducing significant azimuthal magnetic fields, either from a prevalent axial field $B_z$ or by means of a dynamo process without any pre-given $B_z$. Note that $B_\phi \propto 1/R$ would only appear in the extreme case of an isolated axial current, while the other extreme case, $B_\phi \propto R$, would correspond to the case of a homogeneous axial current density in the fluid which is already prone to the kink-type Taylor instability (Seilmayer et al. 2012), even at $\text{Re} = 0$.

Imagine now a real accretion disk with its complicated conductivity distributions in radial and axial direction. For such real disks a large variety of intermediate $B_\phi(R)$ profiles between the extreme cases $\propto 1/R$ and $\propto R$ profiles is well conceivable. Instead of going into those details, one can ask which $B_\phi(R)$ profiles could make HMRI a viable mechanism for destabilizing Keplerian rotation profiles. By defining an appropriate magnetic Rossby number $R_b$ we showed that the instability extends well beyond the LLL, even reaching $\text{Ro} = 0$ when going to $R_b = -0.5$. It should be noted that in this extreme case of uniform rotation the only available energy source of the instability is the magnetic field.

Going then over into the region of positive $\text{Ro}$ in the $\text{Ro} - R_b$-plane, we found a natural connection with the ULL which was a somewhat mysterious conundrum up to present.

The present paper represents a significant extension of the short letter (Kirillov & Stefani 2013). In the first instance, we will present a detailed derivation of the dispersion relation for arbitrary azimuthal modes in viscous, resistive rotational flows under the influence of a constant axial and a superposed azimuthal field of arbitrary radial dependence. For this purpose, we employ the short-wavelength approximation in its rigorous form following Eckhoff (1987), Bayly (1988), Lifschitz & Hameiri (1991), Friedlander & Vishik (1995), Hattori & Fukumoto (2003), and Friedlander & Lipton-Lifschitz (2003).

Second, we will discuss in much more detail the stability map in the $\text{Ro} - R_b$-plane in the inductionless case of vanishing magnetic Prandtl number. For various limits we will discuss a number of strict results concerning the stability threshold and the growth rates. Special focus will be laid on the role that is played by the line $\text{Ro} = R_b$, and by the point $\text{Ro} = R_b = -2/3$ in particular.

Third, we will elaborate the dependence of the instability on the azimuthal wavenumber.

and on the ratio of the axial and radial wavenumbers and establish that the pattern of instability domains in the case of small, but finite $P \mu$, is governed by a periodic band structure found in the inductionless limit.

Next, we will establish connection between dissipation-induced destabilization of Chandrasekhar’s equipartition solution and azimuthal MRI as well as study the links between the Tayler instability and AMRI.

Last, but not least, we will delineate some possible astrophysical and experimental consequences of our findings, although a comprehensive discussions of the corresponding details must be left for future work.

2. Mathematical setting

2.1. Non-linear equations

The standard set of non-linear equations of dissipative incompressible magnetohydrodynamics consists of the Navier-Stokes equation for the fluid velocity $\mathbf{u}$ and of the induction equation for the magnetic field $\mathbf{B}$

\[
\begin{align*}
\frac{\partial \mathbf{u}}{\partial t} + \mathbf{u} \cdot \nabla \mathbf{u} - \frac{1}{\mu_0 \rho} \mathbf{B} \cdot \nabla \mathbf{B} + \frac{1}{\rho} \nabla P - \nu \nabla^2 \mathbf{u} &= 0, \\
\frac{\partial \mathbf{B}}{\partial t} + \mathbf{u} \cdot \nabla \mathbf{B} - \mathbf{B} \cdot \nabla \mathbf{u} - \eta \nabla^2 \mathbf{B} &= 0,
\end{align*}
\]  

(2.1)

where $P = p + \frac{B^2}{2\mu_0}$ is the total pressure, $p$ is the hydrodynamic pressure, $\rho = \text{const}$ the density, $\nu = \text{const}$ the kinematic viscosity, $\eta = (\mu_0 \sigma)^{-1}$ the magnetic diffusivity, $\sigma$ the conductivity of the fluid, and $\mu_0$ the magnetic permeability of free space. Additionally, the mass continuity equation for incompressible flows and the solenoidal condition for the magnetic induction yield

\[
\nabla \cdot \mathbf{u} = 0, \quad \nabla \cdot \mathbf{B} = 0.
\]  

(2.2)

2.2. Steady state

We consider the rotational fluid flow in the gap between the radii $R_1$ and $R_2 > R_1$, with an imposed magnetic field sustained by currents external to the fluid. Introducing the cylindrical coordinates $(R, \phi, z)$ we consider the stability of a steady-state background liquid flow with the angular velocity profile $\Omega(R)$ in helical background magnetic field (a magnetized Taylor-Couette (TC) flow)

\[
\mathbf{u}_0(R) = R \Omega(R) \mathbf{e}_\phi, \quad p = p_0(R), \quad \mathbf{B}_0(R) = B^0_\phi(R) \mathbf{e}_\phi + B^0_z \mathbf{e}_z.
\]  

(2.3)

Note that if the azimuthal component is produced by an axial current $I$, then

\[
B^0_\phi(R) = \frac{\mu_0 I}{2\pi R},
\]  

(2.4)

and, consequently,

\[
\nabla \times \mathbf{B}_0 = \begin{pmatrix} 0 \\ 0 \\ R^{-1} \partial_R (RB^0_\phi) \end{pmatrix} = 0.
\]  

(2.5)

The angular velocity profile of the background TC flow is

\[
\Omega(R) = a + \frac{R}{R^2},
\]  

(2.6)

where

\[
a = \frac{\mu_0 - \hat{\eta}^2}{1 - \hat{\eta}^2} \Omega_1, \quad b = \frac{1 - \mu_0}{1 - \hat{\eta}^2} R_1^2 \Omega_1, \quad \hat{\eta} = \frac{R_1}{R_2}, \quad \mu_0 = \frac{\Omega_2}{\Omega_1}.
\]  

(2.7)
The case of rigid rotation is thus given by $\mu = 1$. The centrifugal acceleration of the background flow (2.6) is compensated by the pressure gradient

$$R\Omega^2 = \frac{1}{\rho} \frac{\partial p_0}{\partial R}.$$  (2.8)

Introducing the hydrodynamic Rossby number (Ro) by means of the relation

$$Ro = \frac{R}{2\Omega} \frac{\partial}{\partial R},$$  (2.9)

we find

$$a = \Omega(1 + Ro).$$  (2.10)

The solid body rotation corresponds to $Ro = 0$, the Keplerian rotation to $Ro = -3/4$, whereas the velocity profile $\Omega(R) \sim R^{-2}$ corresponds to $Ro = -1$.

Similarly, we introduce the magnetic Rossby number (Rb) as

$$Rb = \frac{R}{2B_0 R^{-1}} \frac{\partial}{\partial R} (B_0 \cdot B').$$  (2.11)

Note that $Rb = 0$ results from a linear dependence of the magnetic field on the radius, $B_0(R) \sim R$, as it would be produced by a homogeneous axial current in the fluid. $Rb = -1$ corresponds to the radial dependence given by Eq. (2.4).

2.3. Linearization with respect to non-axisymmetric perturbations

To describe natural oscillations in the neighborhood of the magnetized Taylor-Couette flow we linearize equations (2.1)-(2.2) in the vicinity of the stationary solution (2.3)-(2.5) assuming general perturbations $u = u_0 + u'$, $p = p_0 + p'$, and $B = B_0 + B'$ and leaving only the terms of first order with respect to the primed quantities

$$\partial_t u' + u_0 \cdot \nabla u' + u' \cdot \nabla u_0 - \frac{1}{\rho_0} (B_0 \cdot \nabla B' + B' \cdot \nabla B_0) - \nu \nabla^2 u' = -\frac{1}{\rho} \nabla p' - \frac{1}{\rho_0} \nabla (B_0 \cdot B'),$$

$$\partial_t B' + u_0 \cdot \nabla B' + u' \cdot \nabla B_0 - B_0 \cdot \nabla u' - B' \cdot \nabla u_0 - \eta \nabla^2 B' = 0,$$  (2.12)

where the perturbations fulfill the constraints

$$\nabla \cdot u' = 0, \quad \nabla \cdot B' = 0.$$  (2.13)

Introducing the gradients of the background fields represented by the two $3 \times 3$ matrices

$$\mathcal{U}(R) = \nabla u_0 = \Omega \begin{pmatrix} 0 & -1 & 0 \\ 1 + 2Ro & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$

$$\mathcal{B}(R) = \nabla B_0 = \frac{B_0}{R} \begin{pmatrix} 0 & -1 & 0 \\ 0 & 0 & 0 \\ 1 + 2Rb & 0 & 0 \end{pmatrix},$$  (2.14)

we write the linearized equations of motion in the form

$$(\partial_t + \mathcal{U} + u_0 \cdot \nabla)u' - \frac{1}{\rho_0} (B + B_0 \cdot \nabla) B' - \nu \nabla^2 u' + \frac{1}{\rho} \nabla p' + \frac{1}{\rho_0} \nabla (B_0 \cdot B') = 0,$$

$$(\partial_t - \mathcal{U} + u_0 \cdot \nabla)B' + (B - B_0 \cdot \nabla) u' - \eta \nabla^2 B' = 0.$$  (2.15)

Taking into account the identity

$$\nabla (B_0 \cdot B') = B_0 \times (\nabla \times B') + B' \times (\nabla \times B_0) + (B_0 \cdot \nabla) B' + (B' \cdot \nabla) B_0,$$
we transform equations (2.15) into
\[(\partial_t + \mathbf{u}_0 \cdot \nabla)\mathbf{u}' + \frac{1}{\rho} \nabla p' + \frac{1}{\rho \mu_0} \mathbf{B}_0 \times (\nabla \times \mathbf{B}') + \frac{1}{\rho \mu_0} \mathbf{B}' \times (\nabla \times \mathbf{B}_0) = \nu \nabla^2 \mathbf{u}',
\]
\[(\partial_t - \mathbf{u}_0 \cdot \nabla)\mathbf{B}' + (\mathbf{B} - \mathbf{B}_0 \cdot \nabla)\mathbf{u}' = \eta \nabla^2 \mathbf{B}'. \tag{2.16}\]
Equations (2.16) are simplified for the profile (2.4) in view of the identity (2.5).

3. Geometrical optics equations

We seek for solutions of the linearized equations (2.16) in the form of the geometrical optics approximation, see e.g. Lifschitz (1989) and Friedlander & Lipton-Lifschitz (2003):
\[u'(x, t, \epsilon) = e^{i \Phi(x, t)/\epsilon} \left( u^{(0)}(x, t) + c u^{(1)}(x, t) \right) + c u^r(x, t),
\]
\[B'(x, t, \epsilon) = e^{i \Phi(x, t)/\epsilon} \left( B^{(0)}(x, t) + c B^{(1)}(x, t) \right) + c B^r(x, t),
\]
\[p'(x, t, \epsilon) = e^{i \Phi(x, t)/\epsilon} \left( p^{(0)}(x, t) + c p^{(1)}(x, t) \right) + c p^r(x, t), \tag{3.1}\]
where \(x\) is a vector of coordinates, \(0 < \epsilon < 1\) is a small parameter, \(\Phi\) is a real-valued scalar function that represents the phase of oscillations, and \(u^{(j)}, B^{(j)},\) and \(p^{(j)}, j = 0, 1, r\) are complex-valued amplitudes.

Following Landman & Saffman (1987), Lifschitz (1991), Dobrokhотов & Shafarevich (1992), and Eckhardt & Yao (1995) we assume further in the text that \(\nu = \epsilon^2 \nu'\) and \(\eta = \epsilon^2 \eta'\) and introduce the derivative along the fluid stream lines
\[\frac{D}{Dt} := \partial_t + \mathbf{u}_0 \cdot \nabla. \tag{3.2}\]

Substituting expansions (3.1) into equations (2.16), taking into account the identities
\[(A \cdot \nabla) \Phi B = (A \cdot \nabla \Phi) B + \Phi (A \cdot \nabla) B,
\]
\[(\nabla \times \Phi) B = \Phi (\nabla \times B) + (\nabla \Phi \times B)
\]
as well as the relation
\[\nabla^2 (u') = e^{i \Phi/\epsilon} \left( \nabla^2 + \frac{2}{\epsilon} (\nabla \Phi \cdot \nabla) + i \frac{\nabla^2 \Phi}{\epsilon} - \frac{\nabla \Phi}{\epsilon^2} \right) (u^{(0)} + c u^{(1)}), \tag{3.3}\]
collecting terms at \(\epsilon^{-1}\) and \(\epsilon^0\), and expanding the cross products, we arrive at the system of partial differential equations
\[\frac{D\Phi}{Dt} u^{(0)} + \frac{p^{(0)}}{\rho} \nabla \Phi - \frac{1}{\rho \mu_0} B^{(0)} \cdot \nabla \Phi + \frac{1}{\rho \mu_0} \nabla \Phi (B^{(0)} \cdot B^{(0)}) = 0,
\]
\[\frac{D\Phi}{Dt} B^{(0)} - (B^{(0)} \cdot \nabla) u^{(0)} = 0,
\]
\[\left( \frac{D}{Dt} + \tilde{\nu} \nabla \Phi + \mathbf{u}_0 \right) u^{(0)} + \frac{2}{\rho} \nabla p^{(0)} + i \frac{D\Phi}{Dt} u^{(1)} + i \frac{c}{\rho} \nabla \Phi \tag{3.4}\]
\[+ \frac{1}{\mu_0} B^{(0)} \times \nabla \times B^{(0)} - i \frac{1}{\mu_0} B^{(0)} \times B^{(1)} \times \nabla \Phi + \frac{1}{\mu_0} B^{(0)} \times \nabla \times B_0 = 0,
\]
\[i \frac{D\Phi}{Dt} B^{(1)} + \left( \frac{D}{Dt} + \tilde{\eta} (\nabla \Phi)^2 - \mathbf{u}_0 \right) B^{(0)} + (\mathbf{B} - \mathbf{B}_0 \cdot \nabla) u^{(0)} - i (B^{(0)} \cdot \nabla \Phi) u^{(1)} = 0.
\]
From the solenoidality conditions (2.13) it follows that
\[u^{(0)} \cdot \nabla \Phi = 0, \quad \nabla \cdot u^{(0)} + i u^{(1)} \cdot \nabla \Phi = 0,
\]
\[B^{(0)} \cdot \nabla \Phi = 0, \quad \nabla \cdot B^{(0)} + i B^{(1)} \cdot \nabla \Phi = 0. \tag{3.5}\]
Taking the dot product of the first two of the equations (3.4) with \(\nabla \Phi, u^{(0)}, B^{(0)},\) in
view of the constraints \[3.5\] we arrive at the following system

\[
(\nabla \Phi)^2 \left( \frac{\rho'(0)}{\rho} + \frac{1}{\rho \mu_0}(B_0 \cdot B^{(0)}) \right) = 0, \\
\frac{D\Phi}{Dt} B^{(0)} \cdot B^{(0)} - (B_0 \cdot \nabla \Phi) u^{(0)} \cdot B^{(0)} = 0, \\
\frac{D\Phi}{Dt} B^{(0)} \cdot u^{(0)} - (B_0 \cdot \nabla \Phi) u^{(0)} \cdot u^{(0)} = 0, \\
\frac{D\Phi}{Dt} u^{(0)} \cdot u^{(0)} - \frac{1}{\rho \mu_0} B^{(0)} \cdot B^{(0)} (B_0 \cdot \nabla \Phi) = 0, \\
\frac{D\Phi}{Dt} u^{(0)} \cdot u^{(0)} - \frac{1}{\rho \mu_0} B^{(0)} \cdot u^{(0)} (B_0 \cdot \nabla \Phi) = 0,
\]

that has for \(\nabla \Phi \neq 0\), \(B^{(0)} \neq 0\), and \(u^{(0)} \neq 0\) a unique solution

\[
p^{(0)} = -\frac{1}{\rho_0} (B_0 \cdot B^{(0)}), \quad \frac{D\Phi}{Dt} = 0, \quad B_0 \cdot \nabla \Phi = 0. \quad (3.7)
\]

With the use of the relations \[3.7\] we simplify the last two of the equations \[3.4\] as

\[
(\frac{D}{Dt} + \bar{\nabla}(\nabla \Phi)^2 + \bar{u}t) u^{(0)} - \frac{1}{\rho \mu_0} (B + B_0 \cdot \nabla) B^{(0)} = -\frac{1}{\rho} \left( p^{(1)} + \frac{1}{\rho_0} (B_0 \cdot B^{(1)}) \right) \nabla \Phi, \\
(\frac{D}{Dt} + \bar{\eta}(\nabla \Phi)^2 - \bar{u}t) B^{(0)} + (B - B_0 \cdot \nabla) u^{(0)} = 0.
\]

Eliminating pressure via multiplication of the first of Eqs. \[3.8\] by \(\nabla \Phi\) and taking into account the constraints \[3.5\], we transform equations \[3.8\] into

\[
(\frac{D}{Dt} + \bar{\nabla}(\nabla \Phi)^2 + \bar{u}t) u^{(0)} - \frac{1}{\rho \mu_0} (B + B_0 \cdot \nabla) B^{(0)} = \nabla \Phi \cdot \left[ (\frac{D}{Dt} + \bar{u}t) u^{(0)} - \frac{1}{\rho \mu_0} (B + B_0 \cdot \nabla) B^{(0)} \right] \nabla \Phi, \\
(\frac{D}{Dt} + \bar{\eta}(\nabla \Phi)^2 - \bar{u}t) B^{(0)} + (B - B_0 \cdot \nabla) u^{(0)} = 0.
\]

Differentiating the first of the identities \[3.5\] yields

\[
\frac{D}{Dt} (\nabla \Phi \cdot u^{(0)}) = \frac{D\nabla \Phi}{Dt} \cdot u^{(0)} + \nabla \Phi \cdot \frac{Du^{(0)}}{Dt} = 0. \quad (3.10)
\]

Using the identity \[3.10\], we write

\[
(\frac{D}{Dt} + \bar{\nabla}(\nabla \Phi)^2 + \bar{u}t) u^{(0)} - \frac{1}{\rho \mu_0} (B + B_0 \cdot \nabla) B^{(0)} = \nabla \Phi \cdot \left[ (\frac{D}{Dt} + \bar{u}t) u^{(0)} - \frac{1}{\rho \mu_0} (B + B_0 \cdot \nabla) B^{(0)} \right] \nabla \Phi - \frac{D\nabla \Phi}{Dt} \cdot \frac{Du^{(0)}}{Dt}, \\
(\frac{D}{Dt} + \bar{\eta}(\nabla \Phi)^2 - \bar{u}t) B^{(0)} + (B - B_0 \cdot \nabla) u^{(0)} = 0.
\]

Now we take the gradient of the identity \(D\Phi/Dt = 0\):

\[
\nabla \bar{u}t + \nabla (u_0 \cdot \nabla \Phi) = \bar{u}t \nabla \Phi + (u_0 \cdot \nabla \Phi) + \bar{u}t \nabla \Phi = 0. \quad (3.12)
\]

Denoting \(k = \nabla \Phi\), we deduce from the phase equation \[3.12\] that

\[
\frac{Dk}{Dt} = -\bar{u}t^2 k. \quad (3.13)
\]

Hence, the amplitude (or transport) equations \[3.11\] take the final form

\[
\frac{Dw^{(0)}}{Dt} = - (\mathcal{I} - 2kk^\top |k|^2) u^{(0)} - \bar{\eta} |k|^2 u^{(0)} + \frac{1}{\rho \mu_0} (\mathcal{I} - \frac{kk^\top}{|k|^2}) (B + B_0 \cdot \nabla) B^{(0)}, \\
\frac{DB^{(0)}}{Dt} = \bar{u}t B^{(0)} - \bar{\eta} |k|^2 B^{(0)} - (B - B_0 \cdot \nabla) u^{(0)},
\]

(3.14)
where \( I \) is a \( 3 \times 3 \) identity matrix, cf. Friedlander & Vishik (1995). In the absence of the magnetic field these equations are reduced to that of Landman & Saffman (1987), Lifschitz (1991), Dobrokhotov & Shafarevich (1992), and Eckhardt & Yao (1995) and in the inviscid case to that of Lifschitz & Hameiri (1991).

### 4. Dispersion relation of the amplitude equations

Let the orthogonal unit vectors \( e_R(t), e_\phi(t), \) and \( e_z(t) \) form a basis in a cylindrical coordinate system moving along the fluid trajectory. With \( k(t) = k_R e_R(t) + k_\phi e_\phi(t) + k_z e_z(t), \) \( u(t) = u_R e_R(t) + u_\phi e_\phi(t) + u_z e_z(t), \) and with the matrix \( U \) from (2.14), we find that

\[
\dot{e}_R = \Omega(R) e_\phi, \quad \dot{e}_\phi = -\Omega(R) e_R.
\]

Hence, the equation (3.13) in the coordinate form is

\[
\dot{k}_R - \Omega k_\phi = -\Omega k_\phi - R \partial_R \Omega k_\phi, \quad \dot{k}_\phi + \Omega k_R = \Omega k_\phi, \quad \dot{k}_z = 0.
\]

Therefore,

\[
\dot{k}_R = -R \partial_R \Omega k_\phi, \quad \dot{k}_\phi = 0, \quad \dot{k}_z = 0.
\]

According to Eckhardt & Yao (1995) and Friedlander & Vishik (1995), in order to study physically relevant and potentially unstable modes we have to choose bounded and asymptotically non-decaying solutions of the system (4.2). These correspond to \( k_\phi = 0 \) and \( k_R \) and \( k_z \) time-independent. Denoting \( \alpha = k_z |k|^{-1} \), where \( |k|^2 = k_R^2 + k_z^2 \), we find that \( k_R k_\phi^{-1} = \sqrt{1 - \alpha^2} \) and taking into account relations (A.1) we write the partial differential equations (4.1) for the amplitudes in the coordinate representation

\[
\begin{aligned}
\partial_t u_R^{(0)} &+ \Omega \left( \partial_\phi u_R^{(0)} - u_\phi^{(0)} \right) + \tilde{\nu} |k|^2 u_R^{(0)} + \Omega u_\phi^{(0)} - 2\Omega u_\phi^{(0)} \alpha^2 + B_\rho^0 \frac{R}{\rho \mu R} \alpha \partial_\phi B_\rho^{(0)} - \sqrt{1 - \alpha^2} \partial_\rho B_\phi^{(0)} = 0, \\
\partial_t u_\phi^{(0)} &+ \Omega \left( \partial_\phi u_\phi^{(0)} + u_R^{(0)} \right) + \left( \Omega + 2\Omega R \right) u_\phi^{(0)} + \tilde{\nu} |k|^2 u_\phi^{(0)} - \frac{1}{\rho \mu \alpha} \frac{B_\rho^0}{R} \partial_\phi B_\phi^{(0)} - \frac{B_\rho^0}{\rho \mu \alpha} \partial_\phi B_\rho^{(0)} \right), \\
\partial_t u_z^{(0)} &+ \Omega \partial_\phi u_z^{(0)} + 2\sqrt{1 - \alpha^2} \Omega u_z^{(0)} + \tilde{\nu} |k|^2 u_z^{(0)} + \frac{B_\rho^0 (\alpha^2 - 1) \partial_\phi B_z^{(0)}}{\rho \mu \alpha - R} + \frac{R}{R \rho \mu \alpha} \partial_\phi B_\rho^{(0)} + B_\rho^0 \sqrt{1 - \alpha^2} \partial_\rho B_\phi^{(0)} - \sqrt{1 - \alpha^2} \partial_\rho B_\phi^{(0)} = 0, \\
\partial_t B_R^{(0)} &+ \Omega \left( \partial_\phi B_R^{(0)} - B_\phi^{(0)} \right) + \Omega B_\phi^{(0)} + \tilde{\nu} |k|^2 B_R^{(0)} - B_\rho^0 \partial_\phi u_R^{(0)} - \frac{B_\rho^0}{R} \partial_\phi u_\phi^{(0)} = 0, \\
\partial_t B_\phi^{(0)} &+ \Omega \left( \partial_\phi B_\phi^{(0)} + B_R^{(0)} \right) - \left( \Omega + 2\Omega R \right) B_\phi^{(0)} + \tilde{\nu} |k|^2 B_\phi^{(0)} - B_\rho^0 \partial_\phi u_R^{(0)} + 2Rb \frac{B_\rho^0}{R} u_R^{(0)} - \frac{B_\rho^0}{R} \partial_\phi u_\phi^{(0)} = 0, \\
\partial_t B_z^{(0)} &+ \Omega \partial_\phi B_z^{(0)} + \tilde{\nu} |k|^2 B_z^{(0)} - B_\rho^0 \partial_\phi u_z^{(0)} - \frac{B_\rho^0}{R} \partial_\phi u_\phi^{(0)} = 0.
\end{aligned}
\]
Assuming that the solution to Eqs. (4.3) has the modal form $e^{\gamma t + im_0 \phi + ik_z z}$, we obtain

\[
(\gamma + im_0 \Omega + \overline{\nu}|k|^2)u_R^{(0)} - 2\alpha^2 \Omega u_\phi^{(0)} + 2\alpha^2 \frac{B_0^0}{\rho_\mu R} B_\phi^{(0)} = 0,
\]

\[
-i\alpha \left( \frac{B_0^0}{\rho_\mu} + k_z B_0^0 \right) \frac{\alpha B_0^{(0)} - \sqrt{1 - \alpha^2} B_{\phi}^{(0)}}{\rho_\mu} = 0,
\]

\[
(\gamma + im_0 \Omega + \overline{\nu}|k|^2)u_\phi^{(0)} + 2\Omega(1 + Ro) u_R^{(0)} - \frac{\alpha_\phi B_0^0}{\rho_\mu R} (1 + Rb) B_R^{(0)}
\]

\[
- i\beta_\phi^{(0)} \left( \frac{B_0^0}{\rho_\mu} + k_z B_0^0 \right) = 0,
\]

\[
(\gamma + im_0 \Omega + \overline{\theta}|k|^2)u_\phi^{(0)} + 2\sqrt{1 - \alpha^2} \Omega u_\phi^{(0)} + \frac{B_0^0(\alpha^2 - 1) \alpha B_{\phi}^{(0)}}{\rho_\mu R}
\]

\[
+ \alpha \sqrt{1 - \alpha^2} B_\phi^{(0)} (\alpha - 1) B_{\phi}^{(0)} + i k_z B_\phi^{(0) \sqrt{1 - \alpha^2} \Omega B_{\phi}^{(0)} - (1 - \alpha^2) B_{\phi}^{(0)}} = 0,
\]

\[
(\gamma + im_0 \Omega + \overline{\eta}|k|^2)B_{R}^{(0)} - i u_R^{(0)} \left( \frac{B_0^0}{\rho_\mu} + k_z B_0^0 \right) = 0,
\]

\[
(\gamma + im_0 \Omega + \overline{\theta}|k|^2)B_{\phi}^{(0)} - 2\Omega R_b B_{R}^{(0)} + 2R_b \frac{B_0^0}{\rho_\mu R} u_R^{(0)} - i u_\phi^{(0)} \left( \frac{B_0^0}{\rho_\mu} + k_z B_0^0 \right) = 0,
\]

\[
(\gamma + im_0 \Omega + \overline{\eta}|k|^2)B_{\phi}^{(0)} - 2\Omega R_b B_{R}^{(0)} + 2R_b \frac{B_0^0}{\rho_\mu R} u_R^{(0)} - i u_\phi^{(0)} \left( \frac{B_0^0}{\rho_\mu} + k_z B_0^0 \right) = 0.
\]

(4.4)

cf. e.g. Friedlander & Vishik (1993). Taking into account that $B_{R}^{(0)} k_R + B_{\phi}^{(0)} k_z = 0$ in the short-wavelength approximation, we single out the equations for the radial and azimuthal components of the fluid velocity and magnetic field

\[
(\gamma + im_0 \Omega + \overline{\nu}|k|^2)u_R^{(0)} - 2\alpha^2 \Omega u_\phi^{(0)} + 2\alpha^2 \frac{B_0^0}{\rho_\mu R} B_\phi^{(0)} - \frac{ib_{\phi}^{(0)}}{\rho_\mu} \left( \frac{B_0^0}{\rho_\mu} + k_z B_0^0 \right) = 0,
\]

\[
(\gamma + im_0 \Omega + \overline{\nu}|k|^2)u_\phi^{(0)} + 2\Omega(1 + Ro) u_R^{(0)} - \frac{2B_0^0}{\rho_\mu R} (1 + Rb) B_R^{(0)}
\]

\[
- \frac{ib_{\phi}^{(0)}}{\rho_\mu} \left( \frac{B_0^0}{\rho_\mu} + k_z B_0^0 \right) = 0,
\]

\[
(\gamma + im_0 \Omega + \overline{\eta}|k|^2)B_{R}^{(0)} - i u_R^{(0)} \left( \frac{B_0^0}{\rho_\mu} + k_z B_0^0 \right) = 0,
\]

\[
(\gamma + im_0 \Omega + \overline{\theta}|k|^2)B_{\phi}^{(0)} - 2\Omega R_b B_{R}^{(0)} + 2R_b \frac{B_0^0}{\rho_\mu R} u_R^{(0)} - i u_\phi^{(0)} \left( \frac{B_0^0}{\rho_\mu} + k_z B_0^0 \right) = 0.
\]

(4.5)

Introducing the viscous, resistive, and Alfvén frequencies corresponding to the axial and azimuthal components of the magnetic field:

\[
\omega_\nu = \overline{\nu}|k|^2, \quad \omega_\eta = \overline{\eta}|k|^2, \quad \omega_A = \frac{k_z B_0^0}{\sqrt{\rho_\mu}}, \quad \omega_{A_\phi} = \frac{B_0^0}{R \sqrt{\rho_\mu}}.
\]

(4.6)

so that \( Rb \) is simply

\[
Rb = \frac{R}{2\omega_{A_\phi}} \partial_R \omega_{A_\phi},
\]

(4.7)

we write the amplitude equations (4.3) as

\[
(\gamma + im_0 \Omega + \omega_\nu) u_R^{(0)} - 2\alpha^2 \Omega u_\phi^{(0)} + 2\alpha^2 \frac{\omega_A^{(0)}}{\sqrt{\rho_\mu}} B_\phi^{(0)} - \frac{i\beta_{\phi}^{(0)}}{\sqrt{\rho_\mu}} (m\omega_{A_\phi} + \omega_A) = 0,
\]

\[
(\gamma + im_0 \Omega + \omega_\phi) u_\phi^{(0)} + 2\Omega(1 + Ro) u_R^{(0)} - \frac{2\omega_A^{(0)}}{\sqrt{\rho_\mu}} (1 + Rb) B_R^{(0)} - \frac{i\beta_{\phi}^{(0)}}{\sqrt{\rho_\mu}} (m\omega_{A_\phi} + \omega_A) = 0,
\]

\[
(\gamma + im_0 \Omega + \omega_\eta) B_{R}^{(0)} - i u_R^{(0)} \sqrt{\rho_\mu} (m\omega_{A_\phi} + \omega_A) = 0,
\]

\[
(\gamma + im_0 \Omega + \omega_\phi) B_{\phi}^{(0)} - 2\Omega R_b B_{R}^{(0)} + 2R_b \omega_{A_\phi} \sqrt{\rho_\mu} u_R^{(0)} - i u_\phi^{(0)} \sqrt{\rho_\mu} (m\omega_{A_\phi} + \omega_A) = 0.
\]

(4.8)
The solvability condition written for the above system of equations yields the dispersion relation of the amplitude equations

$$p(\gamma) := \det(H - \gamma E) = 0,$$

where $E$ is the $4 \times 4$ identity matrix and

$$H = \begin{pmatrix}
-i \Omega - \omega_v & 2 \alpha^2 \Omega & \frac{m \omega_A + \omega_A}{\sqrt{\rho \mu}} & -\frac{2 \omega_A \alpha^2}{\sqrt{\rho \mu}} \\
-2 \Omega(1 + R) & -i \Omega - \omega_v & \frac{2 \omega_A}{\sqrt{\rho \mu}}(1 + Rb) & 0 \\
i(m \omega_A + \omega_A) \sqrt{\rho \mu} & 0 & -i \Omega - \omega_\eta & 2 \Omega R \\
-2 \omega A R b \sqrt{\rho \mu} & i(m \omega A + \omega A) \sqrt{\rho \mu} & 2 \Omega R & -i \Omega - \omega_\eta
\end{pmatrix}.  \tag{4.9}$$

The fourth-order polynomial \(^{(4.9)}\)

$$p(\gamma) = (a_0 + ib_0)\gamma^4 + (a_1 + ib_1)\gamma^3 + (a_2 + ib_2)\gamma^2 + (a_3 + ib_3)\gamma + a_4 + ib_4,  \tag{4.11}$$

has complex coefficients, where

$$a_0 = 1, \quad b_0 = 0, \quad a_1 = 2(\omega_\eta + \omega_\nu), \quad b_1 = 4m \Omega,$$
$$a_2 = -4 \alpha^2 \omega_A^2 R b + 4 \alpha^2 \Omega^2 (1 + R) + (\omega_v + \omega_\eta)^2 - 2(3m^2 \Omega^2 - (m \omega_A + \omega_A)^2 - \omega_v \omega_\eta),$$
$$a_3 = 2(\omega_v + \omega_\eta)(-2 \alpha^2 \omega_A^2 R b - (3m^2 \Omega^2 - (m \omega_A + \omega_A)^2 - \omega_v \omega_\eta)) + 8 \alpha^2 \Omega^2 \omega_\eta (1 + R),$$
$$b_2 = \frac{3}{4} a_1 b_1,$$$$
a_4 = ((4 \Omega^2 (\omega_A + m \omega_A)^2 - 4 \Omega^2 m^2 + 4 \Omega^2 \omega_\eta^2) R b + 8 \omega_A \omega_A m \Omega^2 + 4 \Omega^2 \omega_\eta^2 - 4 \Omega^4 m^2) \alpha^2 - \Omega^2 m^2 (\omega_v + \omega_\eta)^2 + (m^2 \Omega^2 - (\omega_A + m \omega_A)^2 - \omega_v \omega_\eta)^2$$
$$+ 4(Rb + 1) \omega_A^2 \alpha^2 (m^2 \Omega^2 - (\omega_A + m \omega_A)^2) + 4 \omega_A^2 \alpha^2 (m^2 \Omega^2 - \omega_v \omega_\eta R b),$$
$$b_4 = -4m \Omega \alpha^2 [(Rb + 1)(\omega_\nu - \omega_\eta) + (Rb + 1)(\omega_\eta + \omega_\nu)] \omega_\eta^2$$
$$-4 \omega_A \Omega \alpha^2 (R \omega_\nu - \omega_\nu) + 2 \omega_\eta \omega_\eta + 2 \omega_\eta \omega_\eta + 2m \Omega (4 \alpha^2 \Omega^2 \omega_\eta (Rb + 1) + (\omega_v + \omega_\eta)(\omega_v \omega_\eta - m^2 \Omega^2 + (\omega_A + m \omega_A)^2)). \tag{4.12}$$

When $Rb = -1$, the dispersion relation is reduced to that derived by Kirillov et al. (2012). In the particular case when $\omega_\nu = 0$, $\omega_\eta = 0$, and $\omega_A = 0$, the coefficients \(^{(4.12)}\) of the dispersion relation exactly coincide with those derived by Friedlander & Vishik (1995) when the quantization constant introduced in that work vanishes and the azimuthal Alfvén frequency $A = A(R)$ and the angular velocity $\Omega = \Omega(R)$ are functions of only the radial coordinate $R$. Hence, according to Eq. \(^{(4.7)}\)

$$\partial_R A = \partial_R \omega_A = \frac{2Rb}{R} \omega_A. \tag{4.13}$$

With the relations \(^{(4.9)}\) and \(^{(4.13)}\), the dispersion relation derived by Friedlander & Vishik (1995) reduces to ours at $\omega_\nu = 0$, $\omega_\eta = 0$, and $\omega_A = 0.$

Note also that in the absence of the magnetic fields, the dispersion relation determined by the matrix $H$ reduces to that derived already by Krueger et al. (1966) for the non-axisymmetric perturbations of the hydrodynamic TC flow. Explicitly, this connection is established in Appendix B. In the presence of the magnetic fields with $Rb = -1$ and $m = 0$, the dispersion relation reduces to that derived by Kirillov & Stefani (2010).
5. Connection to the known stability and instability criteria

Let us compose a matrix filled in with the coefficients of the complex polynomial \( B \) (Kirillov 2013):

\[
B = \begin{pmatrix}
  a_4 & -b_4 & 0 & 0 & 0 & 0 & 0 \\
  b_3 & a_3 & a_4 & -b_4 & 0 & 0 & 0 \\
 -a_2 & b_2 & b_3 & a_3 & a_4 & -b_4 & 0 \\
 -b_1 & -a_1 & -a_2 & b_2 & b_3 & a_3 & a_4 \\
 a_0 & -b_0 & -b_1 & -a_1 & -a_2 & b_2 & b_3 \\
 0 & 0 & a_0 & -b_0 & -b_1 & -a_1 & -a_2 \\
 0 & 0 & 0 & 0 & 0 & a_0 & -b_0
\end{pmatrix}.
\]

(5.1)

The stability criterion by Bilharz (1944) requires positiveness of the determinants of the four diagonal sub-matrices of even order of the matrix \( B \) (Kirillov 2013):

\[
m_1 = \det \begin{pmatrix} a_4 & -b_4 \\ b_3 & a_3 \end{pmatrix} > 0, \quad \ldots, \quad m_4 = \det B > 0
\]

(5.2)

in order that all the roots of the complex polynomial \( B \) have negative real parts.

In the ideal case the dispersion relation of SMRI by Balbus & Hawley (1992) reads as

\[
p(\gamma) = (\gamma^2 + \omega_A^2)^2 + 4\alpha^2\Omega^2(1 + \text{Ro})(\gamma^2 + \omega_A^2) - 4\alpha^2\Omega^2\omega_A^2
\]

and follows from our result when setting \( \omega_{A_0} = 0, \omega_\nu = 0, \) and \( \omega_\eta = 0 \) in the form

\[
p(\gamma) = \gamma^4 + (4\Omega^2\alpha^2\text{Ro} + 4\Omega^2\alpha^2 + 2\omega_A^2)^2 - 4\omega_A^2\Omega^2\alpha^2\text{Ro} + \omega_A^4.
\]

In the dissipative case, the threshold for the Standard MRI is given by the equation \( m_4 = 0 \) with \( \omega_{A_0} = 0 \). This yields the expression found in Kirillov & Stefani (2012)

\[
\text{Ro} = -\frac{(\omega_A^2 + \omega_\nu\omega_\eta)^2 + 4\alpha^2\Omega^2\omega_\eta^2}{4\alpha^2\Omega^2(\omega_A^2 + \omega_\eta^2)}.
\]

(5.3)

When \( \text{Ro} = 0, \Omega = 0, \) and \( m = 0 \) we get an instability condition that extends that of Chandrasekhar (1961) (see also Rüdiger et al. 2010) to the dissipative case

\[
\text{Rb} > \frac{(\omega_\nu\omega_\eta + \omega_A^2)^2 - 4\alpha^2\omega_A^2\omega_{A_0}^2}{4\alpha^2\omega_A^2(\omega_\nu\omega_\eta + m^2\omega_{A_0}^2)}.
\]

(5.4)

On the other hand, under the assumption that \( \Omega = 0 \) and \( \omega_A = 0 \) the dispersion relation is a real polynomial. Hence, by vanishing its constant term we determine the condition for a static instability

\[
\text{Rb} > \frac{(\omega_\nu\omega_\eta + m^2\omega_{A_0}^2)^2 - 4\alpha^2m^2\omega_{A_0}^4}{4\alpha^2\omega_{A_0}^2(\omega_\nu\omega_\eta + m^2\omega_{A_0}^2)}.
\]

(5.5)

When \( \text{Rb} = 0 \) the criterion \( \text{Ro} = 0 \) yields the onset of the standard Taylor (1973) instability at

\[
\omega_{A_0} > \sqrt{\frac{\omega_\nu\omega_\eta}{\alpha^2 - (m \pm \alpha)^2}}.
\]

(5.6)

Another particular case \( \omega_A = 0 \) and \( m = 0 \) yields the following extension of the stability condition by Michael (1954):

\[
\text{Ro} > -1 + \frac{\omega_A^2\omega_\nu}{\Omega^2\omega_\eta} - \frac{\omega_\nu^2}{4\alpha^2\Omega^2}.
\]

(5.7)
Choosing, additionally, \( \omega_{A_o} = 0 \), we reproduce the result of Eckhardt & Yao (1995)

\[
\text{Ro} > -1 - \frac{\omega^2}{4 \alpha^2 \Omega^2}
\]

The ideal Michael criterion

\[
\frac{d}{dR} \left( \Omega^2 R^4 \right) - \frac{R^4}{\mu_0} \frac{d}{dR} \left( \frac{B_0^0}{R} \right)^2 > 0
\]

or

\[
\text{Ro} > -1 + \frac{\omega_{A_o}^2}{\Omega^2}
\]

follows from Eq. (5.7) when \( \omega_{\eta} = \omega_{\nu} \) and \( \omega_{\nu} \rightarrow 0 \) (see also Howard and Gupta (1962)).

Finally, letting in the equation (4.10)

\[
R_b = \text{Ro}, \quad \Omega = \omega_{A_o}
\]

and assuming \( \omega_{\nu} = 0 \) and \( \omega_{\eta} = 0 \), we find that (4.9) has the following roots

\[
\gamma_{1,2} = 0, \quad \gamma_{3,4} = -2i \omega_{A_o} (m \pm \alpha),
\]

indicating marginal stability. Indeed, for the inviscid fluid of infinite electrical conductivity with \( P = \text{const.} \), conditions (5.10) define at \( R_b = \text{Ro} = -1 \) Chandrasekhar’s equipartition solution, which is stable (Chandrasekhar 1956, 1961; Bogoyavlenski 2004).

6. Dispersion relation in dimensionless parameters

The dispersion relation (4.9) of the system (4.8) has the same roots as the equation

\[
\det(\tilde{\mathbf{T}} - \gamma \tilde{\mathbf{E}}) = 0,
\]

where \( \mathbf{T} = \text{diag} (1, 1, (\mu_0)^{-1/2}, (\mu_0)^{-1/2}) \). Let us change in the equation (6.1) the spectral parameter as \( \gamma = \tilde{\gamma} \sqrt{\omega_{\nu} \omega_{\eta}} \) and in addition to the hydrodynamic (Ro) and magnetic (Rb) Rossby numbers introduce the magnetic Prandtl number (Pm), the ratio of the Alfvén frequencies (\( \beta \)), Reynolds (Re) and Hartmann (Ha) numbers as well as the modified azimuthal wavenumber \( n \) as follows

\[
P_m = \frac{\omega_{\nu}}{\omega_{\eta}}, \quad \beta = \frac{\omega_{A_o}}{\omega_{\nu}}, \quad \text{Re} = \frac{\Omega}{\omega_{\nu}}, \quad \text{Ha} = \frac{\omega_{A}}{\sqrt{\omega_{\nu} \omega_{\eta}}}, \quad n = \frac{m}{\alpha}.
\]

Then, the dispersion relation (6.1) transforms into

\[
p(\tilde{\gamma}) = \det \left( \tilde{\mathbf{H}} - \frac{\tilde{\gamma}}{\sqrt{P_m}} \mathbf{E} \right) = 0,
\]

with

\[
\tilde{\mathbf{H}} = \begin{pmatrix}
-\text{inRe} - 1 & 2\text{Re} & \frac{i\text{Ha}(1+n\beta)}{\alpha \sqrt{P_m}} & -\frac{2\beta \text{Ha}}{\sqrt{P_m}} \\
-2\text{Re}(1+\text{Ro}) & -\text{inRe} - 1 & \frac{i\text{Ha}(1+n\beta)}{2\text{Re}(1+\text{Ro})} & -\frac{2\beta \text{Ha}}{\sqrt{P_m}} \\
0 & \frac{i\text{Ha}(1+n\beta)}{\alpha \sqrt{P_m}} & -\text{inRe} - \frac{1}{P_m} & -\frac{2\beta \text{Ha}}{\alpha \sqrt{P_m}} \\
\frac{2\text{Re} \text{Ha}}{\alpha \sqrt{P_m}} & \frac{2\text{Re} \text{Ha}}{\alpha \sqrt{P_m}} & -\frac{2\beta \text{Ha}}{\alpha \sqrt{P_m}} & -\text{inRe} - \frac{1}{P_m}
\end{pmatrix}.
\]

The coefficients of the polynomial (6.3) are explicitly given by Eq. (C.1) in Appendix C.

Next, we divide the equation (6.3) by Re and introduce the eigenvalue parameter

\[
\lambda = \frac{\tilde{\gamma}}{\text{Re} \sqrt{P_m}} = \frac{\tilde{\gamma} \sqrt{\omega_{\nu} \omega_{\eta}}}{\alpha \Omega} = \frac{\gamma}{\alpha \Omega}.
\]
This results in the dispersion relation

\[ p(\lambda) = \det(M - \lambda E) = 0, \quad (6.6) \]

where

\[
M = \begin{pmatrix}
-\frac{i n}{\text{Re}} - \frac{1}{\text{Re}} & \frac{2 \alpha}{\text{Re}} & i(1+n\beta)\sqrt{\frac{N}{R_m}} & -2\alpha\beta\sqrt{\frac{N}{R_m}} \\
-\frac{2(1+Ro)}{\alpha} & -\frac{i n}{\text{Re}} - \frac{1}{\text{Re}} & \frac{2\beta(1+Rb)}{\alpha} & i(1+n\beta)\sqrt{\frac{N}{R_m}} \\
\frac{i(1+n\beta)}{\alpha}\sqrt{\frac{N}{R_m}} & 0 & -\frac{i n}{\text{Re}} - \frac{1}{\text{Re}} & 0 \\
-\frac{-2\beta Rb}{\alpha}\sqrt{\frac{N}{R_m}} & \frac{i(1+n\beta)}{\alpha}\sqrt{\frac{N}{R_m}} & \frac{2Ro}{\alpha} & -\frac{i n}{\text{Re}} - \frac{1}{\text{Re}} \\
\end{pmatrix}, \quad (6.7)
\]

Here, \( \mathcal{N} = \frac{H_a^2}{\text{Re}} \) is the Elsasser number (interaction parameter) and \( R_m = \text{Re}P_m \) is the magnetic Reynolds number. Explicit coefficients of the dispersion relation (6.6) can be found in equation (C 2) of the Appendix C. In the following, we will use the dispersion relations (4.9), (6.3), and (6.6) with different parameterizations in order to facilitate physical interpretation and comparison with the results obtained in astrophysical, MHD, and hydrodynamical communities.

7. Inductionless approximation

In this section, we focus on the inductionless approximation by setting the magnetic Prandtl number to zero \cite{Hollerbach&Rüdiger2005, Priede2011} which is a reasonable approximation for liquid metal experiments as well as for some colder parts of accretion disks.

7.1. The threshold of instability

We put \( P_m = 0 \) into the expressions for \( m_4 \) in equation (5.2). For the coefficient \( m_4 = \det B \) this leads to a great simplification and yields the instability threshold in a compact and closed form:

\[
(1 + Ha^2(n\beta + 1)^2)^2 - 4Ha^2\beta^2(1 + Ha^2(n\beta + 1)^2)Rb - 4Ha^4\beta^2(n\beta + 1)^2 \\
\frac{Ha^4\beta^2(n\beta + 1)^2}{Ha^4\beta^2(n\beta + 1)^2} \frac{2\text{Re}}{1 + Ha^2(n\beta + 1)^2 - 2\beta^2 Rb} \left[ (1 + Ha^2(n\beta + 1)^2 - 2\beta^2 Rb)^2 - 4Ha^4\beta^2(n\beta + 1)^2 \right] (Ro + 1) \\
= \left( \frac{2\text{Re}}{1 + Ha^2(n\beta + 1)^2 - 2\beta^2 Rb} \right)^2. \quad (7.1)
\]

Equation (7.1) can be resolved with respect to the hydrodynamic Rossby number, which yields the critical \( Ro \) as a function of all other parameters. Taking subsequently the limits \( \text{Re} \to \infty \) and \( Ha \to \infty \) we obtain the expressions for the two branches

\[
Ro^\pm = -2 + \frac{(n\beta + 1)^2 - 2\beta^2 Rb \pm \sqrt{(n\beta + 1)^2 - 2\beta^2 Rb)^2 - 4\beta^2(n\beta + 1)^2}}{2\beta^2(n\beta + 1)^2((n\beta + 1)^2 - 2\beta^2 Rb)^{-1}}. \quad (7.2)
\]

At \( n = 0 \) and \( Rb = -1 \) the expressions (7.2) reduce to that derived in the earlier work by \cite{Kirillov&Stefani2011}

\[
Ro^\pm = \frac{4\beta^2 + 1 \pm (2\beta^2 + 1)\sqrt{4\beta^4 + 1}}{2\beta^2}. \quad (7.3)
\]

which after resolution with respect to \( \beta \) coincide with the formulas by \cite{Priede2011}.
7.2. Extremal properties of the critical hydrodynamic Rossby number

For a given magnetic Rossby number, $R_b$, the functions $Ro^\pm(n, \beta)$ take their extrema

$$Ro^\pm_{\text{extr}} = -2 - 4R_b \pm 2\sqrt{2R_b(2R_b + 1)}$$

at the following extremizers

$$\beta^\pm_{\text{extr}} = \frac{-1}{n + \sqrt{-2R_b}}, \quad \beta^-_{\text{extr}} = \frac{-1}{n - \sqrt{-2R_b}}$$

The branch $Ro^-$ $(\beta, n)$ is shown in Fig. 1(a) for $R_b = -25/32$ (this particular value has been chosen since it is the minimum value which leads to destabilization of Keplerian profiles, as we will see below). The maximal value of the hydrodynamic Rossby number is constant along the curves (7.4), see Fig. 1(a,b).

The cross-section of the function $Ro^-(\beta, n)$ at $n = 0$ corresponding to the Helical magnetorotational instability (HMRI) is plotted in Fig. 1(c). In contrast, Fig. 1(d) shows the limit $\beta \to +\infty$

$$Ro^- (n, R_b) = -2 + (n^2 - 2R_b)\frac{n^2 - 2R_b - \sqrt{(n^2 - 2R_b)^2 - 4n^2}}{2n^2}$$

Figure 1. (a) The function $Ro^- (\beta, n)$ given by Eq. (7.2) at $R_b = -25/32$. (b) Its extremizers (7.5) along which the critical hydrodynamic Rossby number attains the maximal value $Ro^- = -3/4$. The cross-section of the function at (c) $n = 0$ (HMRI) and (d) at $\beta \to +\infty$ (AMRI).
corresponding to the azimuthal magnetorotational instability (AMRI).

The function (7.6) attains its maximal value $\text{Ro}_{\text{ext}}$ given by equation (7.4) at

$$n = \pm \sqrt{-2Rb}.$$  \hfill (7.7)

Since by definition (6.2) $n = \frac{\omega_A}{\alpha}$ where $\sqrt{k_0^2 + k_z^2} = \alpha \in [0, 1]$, then for $Rb \in [-1, -0.5]$ the condition (7.7) yields the only possible integer values of the azimuthal wavenumber:

$$m = \pm 1.$$  

This means that the effect of the purely azimuthal magnetic field is most pronounced at the maximal possible range of variation of the hydrodynamic Rossby number for the lowest azimuthal modes with $m = \pm 1$. What is the general dependence of the mode number $m$ on $\alpha$, $Rb$, and the ratio $\omega_A / \omega_A$ of the azimuthal to the axial magnetic fields?

7.3. A band structure periodic in $\alpha$

Let us express $\alpha$ from the equations (7.5) as

$$\alpha = \pm \left( m + \frac{\omega_A}{\omega_A} \right) \frac{1}{\sqrt{-2Rb}}.$$ \hfill (7.8)

The ratio $\omega_A / \omega_A$ being plotted against $\alpha$ at different $m$ and $Rb$ uncovers a regular pattern shown in Fig. 2. The pattern is periodic in $\alpha$ with the period $1/\sqrt{-2Rb}$. On the other hand, the dependence of $\alpha$ on the ratio of the magnetic fields is a continuous piecewise smooth function of the ratio of the magnetic fields inside every vertical ‘band’ with the width $1/(2\sqrt{-2Rb})$ in $\alpha$, see Fig. 2(b). The vertical bands in Fig. 2 are further separated into the cells with the boundaries at

$$\frac{\omega_A}{\omega_A} = \frac{2}{1}, \frac{2}{2}, \frac{2}{3}, \frac{2}{4}, \frac{2}{5}, \frac{2}{6}, \ldots.$$ \hfill (7.9)

Every particular cell in Fig. 2 corresponds to a unique integer azimuthal wavenumber $m$. Note however that the cells with the same $m$ are grouped along the same hyperbolic curve given by equation (7.8).

The curves (7.8) with the slopes of the same sign do not cross. The crossings of two
Instabilities in magnetized rotational flows

Figure 3. (a) The lower (LLL) and the upper (ULL) Liu limits existing at $R_b = -1$ are points on the quasi-hyperbolic curve (7.16) in $R_o - R_b$ plane. (b) A scaled fragment of the limiting curve (7.15) demonstrating that the inductionless forms of the magnetorotational instability exist above the lower Liu limit $R_o_{extr} = 2 - 2\sqrt{2}$ when $R_b > -25/32$. The open circle marks the Keplerian value for the Rossby number $R_o = -3/4$ at $R_b = -25/32$ whereas the black circle corresponds to $R_o = R_b = -2/3$. The dashed diagonal is given by the equation $R_o = R_b$.

hyperbolic curves (7.16) with the integer indices $m_1$ and $m_2$ and slopes of different sign happen at

$$\alpha = \frac{m_1 - m_2}{2\sqrt{-2R_b}} \quad \text{and} \quad \frac{\omega_{A_b}}{\omega_A} = \frac{-2}{m_1 + m_2}, \quad (7.10)$$

which explains the sequence (7.9). Within one and the same band with $\alpha \geq 0$ the cells are encoded by the two interlacing series of integers, e.g. for the third band in Fig. 2(a)

$$m = +1, -2, 0, -3, -1, -4, -2, -5, -3, -6, \ldots, \quad (7.11)$$

which is a mixture of the sequences

$$+1, 0, -1, -2, -3, \ldots \quad \text{and} \quad -2, -3, -4, -5, -6, \ldots,$$

whereas for the second band with $\alpha \geq 0$ in Fig. 2(a) we have

$$m = -1, 0, -2, -1, -3, -2, -4, -3, -5, -4, \ldots, \quad (7.12)$$

which corresponds to the two interlacing sequences

$$-1, -2, -3, -4, -5, \ldots \quad \text{and} \quad 0, -1, -2, -3, -4, \ldots \quad (7.13)$$

Therefore, at the crossings (7.10) with $\alpha \neq 0$ the quadruplet of cells consists of two pairs; each pair corresponding to a different value of the azimuthal wavenumber $m$. At the crossings with $\alpha = 0$ all the four cells in the quadruplet have the same $m$.

7.4. Continuation of the Liu limits to arbitrary $R_b$

The extrema (7.4) can be represented in the form

$$R_o_{extr}^\pm = -1 - (\sqrt{2R_b} \pm \sqrt{1 + 2R_b})^2, \quad (7.14)$$

which is equivalent to the expression

$$R_b = -\frac{1}{8} \frac{(R_o + 2)^2}{R_o + 1}. \quad (7.15)$$
A particular case of equation (7.15) at \( R_b = -1 \) yields the result of Liu et al. (2006), reproduced also by Kirillov & Stefani (2011) and Priede (2011). Solving (7.15) at \( R_b = -1 \), we find that the critical Rossby numbers \( \text{Ro}(Ha, Re, n, \beta) \) given by the equation (7.1) and thus the instability domains lie at \( P_m = 0 \) and \( R_b = -1 \) outside the stratum

\[
2 - 2\sqrt{2} =: \text{Ro}_{\text{LLL}} < \text{Ro}(Ha, Re, n, \beta) < \text{Ro}_{\text{ULL}} := 2 + 2\sqrt{2},
\]

where \( \text{Ro}_{\text{LLL}} \) is the value of \( \text{Ro}_{\text{extr}} \) at the lower Liu limit (LLL) and \( \text{Ro}_{\text{ULL}} \) is the value of \( \text{Ro}_{\text{extr}} \) at the upper Liu limit (ULL) corresponding to the critical values of \( \beta \) given by the equation (7.5).

Fig. 3(a) shows how the LLL and ULL continue to the values of \( R_b \neq -1 \). In fact, the LLL and the ULL are points at the quasi-hyperbolic curve

\[
(R_b - \text{Ro} - 1)^2 - (R_b + \text{Ro} + 1)^2 = \frac{1}{2} (\text{Ro} + 2)^2,
\]

which is another representation of equation (7.15). At \( R_b = -1/2 \) the branches \( \text{Ro}_{\text{extr}}(R_b) \) and \( \text{Ro}^{+}_{\text{extr}}(R_b) \) meet each other. Therefore, the inductionless magnetorotational instability at negative \( R_b \) exists also at positive \( \text{Ro} \) when \( \text{Ro} > \text{Ro}_{\text{extr}}(R_b) \), Fig. 3(a). Notice also the second stability domain at \( R_b > 0 \) and \( \text{Ro} < -1 \).

We see that in the inductionless case \( P_m = 0 \) when the Reynolds and Hartmann numbers subsequently tend to infinity and \( \beta \) and \( n \) are under the constraints (7.5), the maximal possible critical Rossby number \( \text{Ro}_{\text{extr}} \) increases with the increase of \( R_b \). At

\[
R_b \geq -\frac{25}{32} = -0.78125
\]

\( \text{Ro}_{\text{extr}}(R_b) \) exceeds the critical value for the Keplerian flow: \( \text{Ro}_{\text{extr}} \geq -3/4 \).

Therefore, the very possibility for \( B_\phi(R) \) to depart from the profile \( B_\phi(R) \propto R^{-1} \) allows us to break the conventional lower Liu limit and extend the inductionless versions of MRI to the velocity profiles \( \Omega(R) \) as steep as the Keplerian one and even to the less steep profiles, including that of the solid body rotation at \( R_b = -1/2 \), Fig. 3(b).

### 7.5. Scaling law of the inductionless MRI

What asymptotic behavior of the Reynolds and Hartmann numbers at infinity leads to maximization of negative (and simultaneously to minimization of positive) critical Rossby numbers? To get an idea, we investigate extrema of \( \text{Ro} \) as a solution to equation (7.1) subject to the constraints (7.5). Taking, e.g., \( \beta = \beta_{\text{extr}} \) in equation (7.4), differentiating the result with respect to \( Ha \), equating it to zero and solving the equation with respect to \( Re \), we find the following asymptotic relation between \( Ha \) and \( Re \) when \( Ha \to \infty \):

\[
Re = 2Rb\sqrt{3Rb + 2(\sqrt{1 + 2Rb} + \sqrt{2Rb})\beta^3Ha^3} + O(Re).
\]

For example, at \( R_b = -1 \) and \( n = 0 \) we have \( \beta = \beta_{\text{extr}} = 1/\sqrt{2} \). After taking this into account in (7.18) we obtain the scaling law of HMRI found in [Kirillov & Stefani (2010)]

\[
Re = \frac{2 + \sqrt{2}}{2} Ha^3 + O(Re).
\]

Figure 4 shows the domains of the inductionless helical MRI at \( R_b = -0.74 \) when the Hartmann and the Reynolds numbers are increasing in accordance with the scaling law (7.18). The instability thresholds easily penetrate the LLL and ULL as well as the Keplerian line and tend to the curves (7.2) that touch the new limits for the critical Rossby number: \( \text{Ro}_{\text{extr}}(-0.74) \approx -0.726 \) and \( \text{Ro}^{+}_{\text{extr}}(-0.74) \approx 2.646 \). Note that the curves (7.2) correspond also to the limit of vanishing Elsasser number \( N \), because according to the
scaling law (7.18) we have $N \propto 1/\text{Ha}$ as $\text{Ha} \to \infty$. This observation makes the dispersion relation (6.6) advantageous for investigation of the inductionless versions of MRI.

7.6. Growth rates of HMRI and AMRI and the critical Reynolds number

We will calculate the growth rates of the inductionless MRI with the use of the dispersion relation (6.6). Assuming in (6.6) $\text{Rm} := \text{RePm} = 0$, we find the roots explicitly:

$$\lambda_{1,2} = -in + N \left(2\beta^2 \text{Rb} - (n\beta + 1)^2\right) - \frac{1}{\text{Re}} \pm 2\sqrt{X + iY}, \quad (7.20)$$

where

$$X = N^2 \beta^2 \left(\beta^2 \text{Rb}^2 + (n\beta + 1)^2\right) - \text{Ro} - 1, \quad Y = N\beta(\text{Ro} + 2)(n\beta + 1) \quad (7.21)$$

Separating the real and imaginary parts of the roots, we find the growth rates of the inductionless MRI in the closed form:

$$(\lambda_{1,2})_r = N \left(2\beta^2 \text{Rb} - (n\beta + 1)^2\right) - \frac{1}{\text{Re}} \pm \sqrt{2X + 2X^2 + Y^2}. \quad (7.22)$$
Particularly, at \( n = 0 \) we obtain the growth rates of the axisymmetric helical magnetorotational instability in the inductionless case.

Introducing the Elsasser number of the azimuthal field as

\[
N_A := \beta^2 N
\]

and then taking the limit of \( \beta \to \infty \) we obtain from the equation (7.22) the growth rates of the inductionless azimuthal MRI:

\[
(\lambda_{1,2})_r = N_A(2Rb - n^2) - \frac{1}{Re} \pm \sqrt{2} \times \sqrt{N_A^2(Rb^2 + n^2) - Ro - 1 + \sqrt{N_A^2(Rb^2 + n^2) - Ro - 1}^2 + N_A^2(Ro + 2)^2n^2}.
\]  

In the inviscid limit \( Re \to \infty \) the term \( \frac{1}{Re} \) vanishes in the expressions (7.22) and (7.24).

On the other hand, in the viscous case the condition \( (\lambda_{1,2})_r > 0 \) yields the critical hydrodynamic Reynolds number beyond which inductionless MRI appears. For example,
Instabilities in magnetized rotational flows

Figure 6. $Ro = -0.75$. Row (a): The growth rates $\lambda_r > 0$ of viscous ($Re = 800$) HMRI ($n = 0$) in the inductionless ($Pm = 0$) limit in projection onto the $N - \beta$ plane. Row (b): The same in the inviscid ($Re \to \infty$) limit. Row (c): The growth rates $\lambda_r > 0$ of AMRI ($\beta \to \infty$) in the inductionless and inviscid limit in projection onto the $N_A - n$ plane. The open circles mark the maxima of $\lambda_r$. Row (a): $\beta \approx 0.830$, $N \approx 0.153$, $\lambda_r \approx 0.002$; $\beta \approx 0.848$, $N \approx 0.193$, $\lambda_r \approx 0.004$; $\beta \approx 0.869$, $N \approx 0.236$, $\lambda_r \approx 0.007$. Row (b): $\beta \approx 0.830$, $N \approx 0.153$, $\lambda_r \approx 0.003$; $\beta \approx 0.848$, $N \approx 0.193$, $\lambda_r \approx 0.005$; $\beta \approx 0.869$, $N \approx 0.236$, $\lambda_r \approx 0.008$. Row (c): $n \approx 1.204$, $N_A \approx 0.105$, $\lambda_r \approx 0.003$; $n \approx 1.180$, $N_A \approx 0.139$, $\lambda_r \approx 0.005$; $n \approx 1.151$, $N_A \approx 0.178$, $\lambda_r \approx 0.008$.

from the equation (7.22) we find the following criterion for the onset of the instability:

$$Re > \frac{1}{N \left(2\beta^2 Rb - (n\beta + 1)^2\right) + \sqrt{2X + 2\sqrt{X^2 + Y^2}}}.$$  \hspace{1cm} (7.25)

With $n = 0$ the criterion (7.25) corresponds to the axisymmetric HMRI. A similar criterion for the onset of AMRI follows from the expression (7.24).

The critical hydrodynamic Reynolds number for a Keplerian flow at $Rb = -0.75$ is plotted in Fig. 5 as a function of the Elsasser number and (Fig. 5(a)) $\beta$ in case of the axisymmetric HMRI and (Fig. 5(b)) $n$ in case of the non-axisymmetric AMRI. In both cases the minimal $Re$ at the onset of instability is about 200.
Consider the Taylor expansion of the eigenvalues (7.20) with respect to the Elsasser number $N$ in the vicinity of $N = 0$
\[
\lambda_{1,2} = -i(n \mp 2\sqrt{Ro + 1}) - \frac{1}{Re} + N \left(-\left(n\beta + 1\right)^2 + 2\beta^2 Rb \pm \beta \frac{(Ro + 2)}{\sqrt{Ro + 1}}(n\beta + 1)\right) + O(N^2). \tag{7.26}
\]
Expressions (7.20) and (7.26) generalize the result of Priede (2011) to the case of arbitrary $n$, $Re$, and $Rb$ and exactly coincide with it at $n = 0$, $Re \to \infty$, and $Rb = -1$.

In the absence of the magnetic field ($N = 0$) the eigenvalues $\lambda_{1,2}$ correspond to damped inertial waves. According to (7.25) at finite $Re$ there exists a critical finite $N > 0$ that is necessary to trigger destabilization of the inertial waves by the magnetic field, see Fig. 5 and Fig. 6(a). However, as the expansion (7.26) demonstrates, in the limit $Re \to \infty$ the inductionless magnetorotational instability occurs when the effect of the magnetic field is much weaker than that of the flow — even when the Elsasser number is infinitesimally small, Fig. 6(b,c).

In the inviscid case the boundary of the domain of instability (7.25) takes the form
\[
N = \pm 2\sqrt{\frac{\beta^2(3R\beta + 2)^2(n\beta + 1)^2 - ((n\beta + 1)^2 - 2\beta^2 Rb)^2(Ro + 1)}{(n\beta + 1)^2 - 4\beta^2(Rb + 1)(n\beta + 1)^2}}. \tag{7.27}
\]
The lines (7.27) bound the domain of non-negative growth rates of HMRI in Fig. 6(b).

When $Ro = Rb$, the stability boundary has a self-intersection at
\[
n = -\frac{1}{\beta} \pm 2\sqrt{Rb + 1}, \quad N = \pm 1 \frac{1}{2\beta^2} \frac{-(3Rb + 2)}{(Rb + 1)(Rb + 2)}. \tag{7.28}
\]
For example, when $Rb = Ro = -0.75$ and $n = 0$, the intersection happens at $\beta = 1$ and $N = \sqrt{5}/5$, Fig. 6(b). If $Rb = Ro = -0.75$ and $\beta \to \infty$, the intersection point is at $n = 1$ and $N_A = \sqrt{5}/5$, Fig. 6(c). In general, the intersection exists at $N \neq 0$ for
\[
Ro = Rb < -\frac{2}{3}. \tag{7.29}
\]
At $Ro = Rb = -\frac{2}{3}$ the intersection occurs at $N = 0$.

In Fig. 6 we see that when $Ro < -\frac{2}{3}$ and $Ro > Rb$, the instability domain consists of two separate regions. In the case when $Ro < -\frac{2}{3}$ and $Ro < Rb$, the two regions merge into one. When the condition (7.29) is fulfilled, the two sub-domains touch each other at the point (7.28). At $Ro = Rb = -\frac{2}{3}$ the lower region shrinks to a single point which simultaneously is the intersection point (7.28) with $N = 0$.

On the other hand, given $Ro < -2/3$ and decreasing $Rb$ we find that the single instability domain tends to split into two independent regions after crossing the line $Ro = Rb$. The further decrease in $Rb$ yields diminishing the size of the lower instability region, see Fig. 6. At which $Rb$ does the lower instability region completely disappear?

Clearly, the lower region disappears when the roots of the equation $N(n) = 0$ become complex. From the expression (7.27) we derive
\[
(n\beta + 1)^2 \pm \beta \frac{Ro + 2}{\sqrt{Ro + 1}}(n\beta + 1) - 2\beta^2 Rb = 0. \tag{7.30}
\]
The equations (7.30) have the roots $n$ complex if and only if their discriminant is negative:
\[
\frac{(Ro + 2)^2}{Ro + 1} + 8Rb < 0. \tag{7.31}
\]
which is simply the domain with the boundary given by the curve of the Liu limits (7.15)
that is shown in Fig. 3. Note that $R_b = -2/3$ and $Ro = -2/3$ satisfy the equation
(7.15), which indicates that the line $Ro = R_b$ is tangent to the curve (7.15) at the point
$(-2/3, -2/3)$ in the Ro-Rb plane, see Fig. 3(b).

Finally, we notice that the left hand side of the equation (7.30) is precisely the coef-
ficient at $N$ in the expansion (7.26). In the inviscid case it determines the limit of the
stability boundary as $N \to 0$, quite in accordance with the scaling law (7.18). Resolving
the equation (7.30) with respect to $Ro$, we exactly reproduce the formula (7.2). At
$n = 0$ and $R_b = -1$ the equation (7.30) exactly coincides with that obtained by Priede (2011).

8. HMRI and AMRI at small, but finite $P_m$

An advantage of the inductionless limit discussed above is the considera-
tble simplification of dispersion relations at $P_m = 0$ or $R_m = 0$ that yields expressions for growth rates
and stability criteria in explicit and closed form. Real physical situations are character-
ized, however, by small but finite values of the magnetic Reynolds and Prandtl numbers.
Below, we demonstrate numerically that HMRI and AMRI exist also when $P_m \neq 0$ or
$R_m \neq 0$. It turns out that, quite remarkably, the pattern of the stability domains keeps
the structure that we have found in the inductionless case. Moreover, the instability cri-
tera of the inductionless limit serve as rather accurate guides in the physically more
realistic situation of finite $P_m$.

8.1. Islands of HMRI at various integer $n$ and their reconnection

Consider the dispersion relation (6.3) and substitute its coefficients (C 1) into the Bil-
harz matrix (5.1). Applying the Bilharz criterion (5.2) to the result, we find that it is
the condition of vanishing the determinant of the Bilharz matrix that determines the
instability threshold. Fixing the Rossby number at the Keplerian value $Ro = -0.75$ and
assuming some reasonable values for the Hartmann and Reynolds numbers, e.g. $Ha = 30$
and $Re = 40000$, we choose the magnetic Rossby number slightly to the right of the line
$Ro = R_b$, which according to the criterion (7.17) should result in instability at least in
the inductionless case. For various integer modified azimuthal wavenumbers $n$ we plot
the instability domains in the $\beta - P_m$ plane, Fig. 7(a,b).

We see that at every integer $n$ there are several instability islands (curiously resembling
those originating in a pure hydrodynamical Taylor-Couette problem (Altmeyer et al.
2011)). As is visible in Fig. 7(b) they tend to group into two clusters.

The first cluster consists of the islands situated at $P_m < 10^{-5}$ and containing intervals
of the positive $\beta$-axis at all $n$ but $n = +1$, Fig. 7(a). Note that the modified azimuthal
wavenumber $n$ corresponding to these islands follow exactly the sequence (7.11) that we
have found in the inductionless case! The growth rates, i.e. the real parts of the roots
$\lambda$ defined via relations (6.5), are plotted in Fig. 7(c) for a fixed value of $P_m$ that cuts
this cluster along a vertical line. Fig. 7(d) demonstrates the growth rates at various $\beta$
corresponding to particular values of $n$. We see that for all $n$ but $n = +1$ the growth
rates tend to some positive values as $P_m \to 0$ indicating a smooth transition to the
inductionless magnetorotational instabilities that occur both for axisymmetric ($n = 0$)
and non-axisymmetric ($n \neq 0$) perturbations. This seems to be the main reason for the
manifestation of the sequence (7.11) in the pattern of the instability islands of Fig. 7(c).

The second cluster of the instability islands occupies the region at $P_m > 10^{-5}$ and
is encoded by the sequence (7.12), see Fig. 7(b). We see that the islands of the two
clusters tend to form quadruplets. Each quadruplet consists of the two pairs of islands
corresponding to the indices $n$ that differ by 2, for example: $0$ and $-2$, $-1$ and $-3$, $-2$
Figure 7. $Ha = 30$, $Ro = -0.75$, $Re = 40000$, $Rb = -0.755$. (a,b) Islands of low $Pm$ magnetorotational instability (HMRI for $n = 0$ and AMRI for $n \neq 0$) corresponding to different modified azimuthal wave numbers $n$. (c,d) The growth rates $\lambda_r$ of the perturbation (c) as functions of $\beta$ at $Pm = 4 \cdot 10^{-6}$ and different $n$ and (d) as functions of $Pm$ at different $n$ and $\beta$.

Figure 8. Subsequently reconnecting instability islands at $Ha = 30$, $Ro = -0.75$, $Re = 40000$ and growing $Rb > -0.75$: (a) $Rb = -0.74933$, (b) $Rb = -0.747$, and (c) $Rb = -0.742$. 
Instabilities in magnetized rotational flows

and $-4$ etc. Each quadruplet whose pairs are labeled with the indices $n_i, n_j \leq 0$ tends to be centered at $\beta = \beta_{ij}$, where

$$\beta_{ij} = -\frac{2}{n_i + n_j},$$

(8.1)

which is exactly the second of the equations (7.10). Moreover, the whole pattern of the instability islands in Fig. 7(b) repeats the pattern of cells in the second and third bands shown in Fig. 2(a).

It is natural to ask what are the conditions for reconnection of the islands in the pairs that constitute every particular quadruplet. To get an idea we play with the two Rossby numbers in Fig. 8. We fix $Ro = -0.75$ and slightly increase $Rb$. As a result, at $Rb = -0.74933$ the islands with the indices $n = -2$ and $n = 0$ reconnect at $\beta_{-2,0} = 1$, Fig. 8(a). At $Rb = -0.747$ these islands overlap whereas the islands in the next quadruplet with $n = -3$ and $n = -1$ reconnect at $\beta_{-3,-1} = -1/2$, Fig. 8(b). At $Rb = -0.742$ the reconnection happens in the third quadruplet at $\beta_{-4,-2} = 1/3$, and so on, Fig. 8(c).

This sequence of the reconnections indicates the special role of the line $Ro = Rb$ which seems to be even more pronounced in the inviscid limit ($Re \to \infty$). In the following we check these hypotheses when the magnetic field has only the azimuthal component which corresponds to the limit $\beta \to \infty$.

8.2. AMRI as a dissipation-induced instability of Chandrasekhar’s equipartition solution

In the matrix (6.7) let us replace via the relation (7.23) the Elsasser number $N$ of the axial field with the Elsasser number of the azimuthal field $N_A$ and then let $\beta \to \infty$. If, additionally

$$N_A = Rm$$

(8.2)

and

$$Ro = Rb,$$

(8.3)

then in the ideal limit ($Re \to \infty$, $Rm \to \infty$) the roots of the dispersion relation (6.6) are

$$\lambda_{1,2} = 0, \quad \lambda_{3,4} = -2i(n \pm 1).$$

(8.4)

With the use of the relations (6.2) it is straightforward to verify that the condition (8.2) requires that $\Omega = \omega_{A\phi}$. Thus, the conditions (8.2) and (8.3) are equivalent to (5.10), which at $Rb = Ro = -1$ define the Chandrasekhar equipartition solution (Kirillov et al. 2014) belonging to a wide class of exact stationary solutions of MHD equations for the case of ideal incompressible infinitely conducting fluid with total constant pressure that includes even knotted flows (Golovin & Krutikov 2012). It is well-known that the Chandrasekhar equipartition solution is marginally stable (Chandrasekhar 1956, 1961; Bogoyavlenski 2004). According to equation (8.4) the marginal stability is preserved in the ideal case also when $Rb = Ro \neq -1$. Will the roots (8.4) acquire only negative real parts with the addition of electrical resistivity?

In general, the answer is no. Indeed, under the constraints (8.2) and (8.3) in the limit of vanishing viscosity ($Re \to \infty$) the Bilharz criterion applied to the dispersion relation (6.6) gives the following threshold of instability

$$16(n^2 - Rb^2)(n^2 - Rb - 2)^2Rm^4 + (n^6 - 12n^2Rb^2 + 32n^2(Rb + 1) - 16Rb^2(Rb + 2))Rm^2 + 4Rb^2 + 4n^2(Rb + 1) = 0.$$  

(8.5)

In the $(n, Rb, Rm)$ space the domain of instability is below the surface specified by
Figure 9. (a) The threshold of instability (8.5) at $N_A = R_m$ and $Re \to \infty$ in the $(n, R_b, R_m)$ space and (b) its projection onto $R_b - n$ plane. The increase in $R_m$ makes the instability domain more narrow so that in the limit $R_m \to \infty$ it degenerates into a ray (dashed) on the straight line (8.6) that emerges from the point (open circle) with the coordinates $n = \frac{2\sqrt{3}}{3}$ and $R_b = -\frac{2}{3}$ and passes through the point with $n = 1$ and $R_b = -1$.

Figure 10. At $n \approx 1.27842$ (a) Azimuthal MRI corresponding to $R_o = -1$ and $R_b = -1$ with the minimal $Re \approx 4.99083$ and (b) Tayler instability corresponding to $R_o = 0$ and $Re = 0$. The open circle marks the onset of the standard TI at $R_b = 0$ with the critical $H_b \approx 1.04117$.

equation (8.5), see Fig. 9(a). When the electrical resistivity is vanishing, the cross-sections of the instability domain in the $R_b - n$ plane become smaller and in the limit $R_m \to \infty$ they tend to the ray on the line

$$R_b = -\frac{2}{3} + \frac{n\sqrt{3} - 2}{3(2 - \sqrt{3})}$$

(8.6)

that starts at the point with the coordinates $n = \frac{2\sqrt{3}}{3}$ and $R_b = -\frac{2}{3}$ and passes through the point with $n = 1$ and $R_b = -1$, Fig. 9(b). For example, at $R_o = R_b = -\frac{3}{4}$ the
Instabilities in magnetized rotational flows

27
equation (8.6) yields

\[ n = \frac{1}{4} + \frac{\sqrt{3}}{2}. \]  \hspace{1cm} (8.7)

On the contrary, when the magnetic Reynolds number \( R_m \) decreases, the instability domain widens up and in the inductionless limit at \( R_m = 0 \) it is bounded by the curve

\[ R_b = \frac{n(n - \sqrt{n^2 + 4})}{2}. \]  \hspace{1cm} (8.8)

The wide part of the instability domain shown in Fig. 9(a) that exists at small \( R_m \) represents the azimuthal magnetorotational instability (AMRI). We see that this instability quickly disappears with the increase of \( R_m \) or \( R_b \). On the other hand, the ideal solution with the roots (8.4) that corresponds to the limit \( R_m \rightarrow \infty \) is destabilized by the electrical resistivity. For \( n \) given by equation (8.7) we have, for example, an unstable root \( \lambda \approx 0.00026 - 0.00493 i \) at \( R_m = 100 \). In general, if \( R_b \) and \( n \) satisfy (8.6), then already an infinitesimally weak electrical resistivity destabilizes the solution specified by the constraints (8.2) and (8.3) at vanishing kinematic viscosity that includes Chandrasekhar’s equipartition solution as a special case. This dissipation-induced instability (Kirillov 2009, 2013) further develops into the AMRI with \( R_m \) decreasing to zero.

9. Transition from AMRI to the Tayler instability

The Tayler instability (Tayler 1973; Rüdiger & Schultz 2010) is a current-driven, kink-type instability that tapers into the magnetic field energy of the electrical current in the fluid. Although its plasma-physics counterpart has been known for a long time, its occurrence in a liquid metal was observed only recently (Seilmayer et al. 2012). In the context of the on-going liquid-metal experiments in the frames of the DRESDYN project (Stefani et al. 2012) it is interesting to get an insight on the transition between the azimuthal magnetorotational instability and the Tayler instability.

Consider the instability threshold (7.1) obtained in the inductionless approximation (\( P_m = 0 \)). Let us introduce the Hartmann number corresponding to the pure azimuthal magnetic field as

\[ H_b := \beta H_a, \]  \hspace{1cm} (9.1)

so that \( N_A = \frac{H_b^2}{R_e} \). Substituting (9.1) into (7.1) and then letting \( \beta \rightarrow \infty \), we find

\[ Re^2 = \frac{(1 + H_b^2 n^2)^2 - 4H_b^2 R_b(1 + H_b^2 n^2) - 4H_b^4 n^2)(1 + H_b^2 (n^2 - 2R_b))}{4(H_b^4 R_o^2 n^2 - (1 + H_b^2 (n^2 - 2R_b))^2 - 4H_b^5 n^2)(R_o + 1)}. \]  \hspace{1cm} (9.2)

Note that the expression (9.2) can also be derived from the equation (7.24).

Consider the threshold of instability (9.2) in the two special cases corresponding to the lower left and the upper right corners of the \( R_o - R_b \) diagram shown in Fig. 8(b). At \( R_o = -1 \) and \( R_b = -1 \) the function \( Re(n, H_b) \) that bounds the domain of AMRI has a minimum \( Re \approx 4.99983 \) at \( n \approx 1.27842 \) and \( H_b \approx 0.61185 \), see Fig. 10(a).

Putting \( Re = 0 \) in (9.2), we find the threshold for the critical azimuthal magnetic field

\[ R_b = \frac{(H_b^2 n^2 + 1)^2 - 4H_b^4 n^2}{4H_b^2(1 + H_b^2 n^2)}. \]  \hspace{1cm} (9.3)

that destabilizes electrically conducting fluid at rest (cf. criterion (5.5)). At \( R_b = 0 \) expression (9.3) gives the value of the azimuthal magnetic field at the onset of the standard
Figure 11. In the assumption that $Ro(R_b) = -\sqrt{-R_b^2 - 2R_b}$ and $n \approx 1.27842$ (a) The domain of the inductionless instability bounded by the surface (9.2) in the $(H_b, R_b, Re)$ space and its cross-sections at (b) $Re = 5.4$, (c) $Re = 5.734$, and (d) $Re = 6$. The domains of TI and AMRI reconnect via a saddle point at $Re = 5.734$.

Tayler instability (cf. criterion (5.6))

$$H_b = \frac{1}{\sqrt{1 - (1 - |n|)^2}}.$$  \hfill (9.4)

For example, at $n \approx 1.27842$

$$H_b \approx 1.04117,$$  \hfill (9.5)

see Fig. 11(b). In the following, we prefer to extend the notion of the Tayler instability to the whole domain bounded by the curve (9.3) and shown in gray in Fig. 11(b).

How the domains of the Tayler instability and AMRI are related to each other? Is there a connection between them in the parameter space?

Let us look at the $Ro - R_b$ diagram shown in Fig. 3(b). To connect the two opposite corners of it we obviously need to take a path that lies below the line $Ro = R_b$. Indeed, any path above this line penetrates the limiting curve (7.15) which creates an obstacle for connecting the two regions shown in Fig. 10. On the contrary, any path below the diagonal in Fig. 3(b) lies within the instability domain which opens a possibility to
connect the regions of AMRI and TI. Therefore, it is the dependency $Ro(Rb)$ that controls the transition from the azimuthal magnetorotational instability to the Taylor instability.

Assume, for example, that $Ro = -\sqrt{-Rb^2 - 2Rb}$, which is a part of the unit circle that connects the point with $Rb = -1$ and $Ro = -1$ and the point with $Rb = 0$ and $Ro = 0$ in Fig. 3(b). Substituting this dependency into the expression (9.2), we can plot the domain of instability in the $(Hb, Rb, Re)$ space for a given $n$, Fig. 11(a). The cross-section of the domain at $Re = 0$ yields exactly the region of the Taylor instability shown in Fig. 10(a). The cross-section at $Rb = -1$ is the domain of AMRI in Fig. 11(b).

At $Re < 4.99083...$ the azimuthal MRI with $n \approx 1.27842$ at $Rb = -1$ does not exist. With the increase in the Reynolds number the island of AMRI originates, Fig. 11(b), that further reconnects with the viscosity-modified domain of TI at a saddle point, Fig. 11(c). At higher values of $Re$ the two domains merge into one, Fig. 11(d).

What happens with the inductionless instability diagram of Fig. 11 when the magnetic Prandtl number takes finite values? It turns out that at $Pm \ll 1$ the difference is very

Figure 12. The instability domain in the assumption that magnetic Prandtl number takes a finite value $Pm = 0.05$, $n = 1.27842$, and $Ro = -\sqrt{-Rb^2 - 2Rb}$ at (a) $Re = 0$, (b) $Re = 3.8$, (c) $Re = 3.958$, (d) $Re = 4.2$. 
small and is not qualitative. Moreover, at Re = 0 the domain of the Tayler instability is still given by equation (9.3) and thus coincides with that shown in Fig. 10(b). Nevertheless, the critical Reynolds number at the saddle point and at the onset of AMRI slightly decreases with the increase in Pm, Fig. 12.

Finally, we plot in Fig. 13(a) the growth rates $\lambda_r(H_b)$ as Rb varies from $-1$ to 0. One can see that the growth rates of the Tayler instability monotonously increase and become positive at $H_b > 1$. When Rb is smaller than about $-0.5$, the function $\lambda_r(H_b)$ has a maximum that can both lie below zero and exceed it in dependence on Rb. The latter weak instability is the azimuthal magnetorotational instability.

In Fig. 13(b) the movement of the roots corresponding to TI and AMRI is presented. There are indications that the origin of the both instabilities might be related to the splitting of a multiple zero root. Note that in the inductionless case the detailed analysis of the roots movement and their bifurcation is possible with the use of equations (7.20) and (7.21). We leave this for a future work.

10. Conclusion

Using the short-wavelength approximation, we have considered the stability condition of a rotating flow under the influence of a constant vertical and an azimuthal magnetic field with arbitrary radial dependence. In the limit of vanishing magnetic Prandtl number as well as for small, but finite Pm, we have shown that Keplerian profiles can well be destabilized by HMRI or AMRI if only the azimuthal field profile is slightly shallower than $1/R$. We have also shown that Chandrasekhar’s equipartition solution, i.e. the line where the hydrodynamic and the magnetic Rossby number are equal, plays an essential point for the connectedness of the instability domain.

With view on astrophysical applications one has definitely to note that any shallower than $1/R$ profile of $B_\phi$ would require some finite magnetic Reynolds number for the necessary induction effects to occur. Nevertheless, our results still provide a real extension of the applicability of MRI, since the Lundquist numbers are allowed to be arbitrarily small, although the growth rate, which is proportional to the interaction parameter, would then be rather small.
The consequences of our findings for those parts of accretion disks with small magnetic Prandtl numbers are still to be elaborated. The action of MRI in the dead zones of protoplanetary disks is an example for which the extended parameter region might have consequences. Particular attention should also be given to the possibility of quasi-periodic oscillations which might easily result from the sensitive dependence of the action of HMRI on the radial profile of of $B_\phi$ and the ratio of the latter to $B_z$. We notice however that pure hydrodynamical scenarios of transition to turbulence in the dead zones had also been proposed (Marcus et al. 2013).

As for liquid metal experiments, our results give strong impetus for a special set-up in which the magnetic Rossby number can be adjusted by using two independent electrical currents, one through a central, insulated rod, the second one through the liquid metal. A liquid sodium experiment dedicated exactly to this problem is presently being designed in the framework of the DRESDYN project (Stefani et al. 2012). Apart from this, the recently observed, and numerically confirmed, strong sensitivity of AMRI on a slight symmetry breaking of an external magnetic field (Seilmayer et al. 2013) may also be related to our findings.

**Appendix A. Some technical details**

For convenience, we provide here explicit expressions for the vectors $(B_0 \cdot \nabla)u^{(0)}$, $(B_0 \cdot \nabla)B^{(0)}$, and $(u_0 \cdot \nabla)u^{(0)}$ in cylindrical coordinates:

$$(B_0 \cdot \nabla)u^{(0)} = \begin{pmatrix}
\frac{B_0^0}{R} \partial_\phi u^{(0)}_R + B_0^0 \partial_z u^{(0)}_R - \frac{B_0^0}{R} u^{(0)}, \\
\frac{B_0^0}{R} \partial_\phi u^{(0)}_\phi + B_0^0 \partial_z u^{(0)}_\phi + \frac{B_0^0}{R} u^{(0)}, \\
\frac{B_0^0}{R} \partial_\phi u^{(0)}_z + B_0^0 \partial_z u^{(0)}_z
\end{pmatrix},$$

$$(B_0 \cdot \nabla)B^{(0)} = \begin{pmatrix}
\frac{B_0^0}{R} \partial_\phi B^{(0)}_R + B_0^0 \partial_z B^{(0)}_R - \frac{B_0^0}{R} B^{(0)}_R, \\
\frac{B_0^0}{R} \partial_\phi B^{(0)}_\phi + B_0^0 \partial_z B^{(0)}_\phi + \frac{B_0^0}{R} B^{(0)}_\phi, \\
\frac{B_0^0}{R} \partial_\phi B^{(0)}_z + B_0^0 \partial_z B^{(0)}_z
\end{pmatrix},$$

$$(u_0 \cdot \nabla)u^{(0)} = \begin{pmatrix}
u_0^0 \partial_\phi u^{(0)}_R + \frac{u_0^0}{R} (\partial_\phi u^{(0)}_R - u^{(0)}_\phi) + u_0^0 \partial_z u^{(0)}_R, \\
u_0^0 \partial_\phi u^{(0)}_\phi + \frac{u_0^0}{R} (\partial_\phi u^{(0)}_\phi + u^{(0)}_R) + u_0^0 \partial_z u^{(0)}_\phi, \\
u_0^0 \partial_\phi u^{(0)}_z + \frac{u_0^0}{R} \partial_\phi u^{(0)}_z + u_0^0 \partial_z u^{(0)}_z
\end{pmatrix} . \quad (A \, 1)$$

**Appendix B. Connection to the work of Krueger et al. (1966)**

The linearized equations derived in the small gap approximation by Krueger et al. (1966) have the form

$$L(D^2 - (k_z d)^2)u' = -(k_z d)^2 T \Omega_1(x)v' , \quad Lv' = u' , \quad (B \, 1)$$
and, finally, Simplifying this equation yields

\[ \sigma = \omega d^2/\nu, \text{ and } k = m \sqrt{-\frac{\Omega_1}{\nu}}. \]

The coefficient \( a \) is defined by Eq. (2.10). Then,

\[ L = -\frac{d^2}{\nu} (\nu(k_R^2 + k_z^2) + i(\omega + m\Omega_1\Omega_l)) \]

\[ = -\frac{d^2}{\nu} (\nu|k|^2 + i(\omega + m\Omega_1\Omega_l)) = -\frac{d^2}{\nu} (\omega + i(\omega + m\Omega_1\Omega_l)). \tag{B 3} \]

Consequently, the first equation in (B 1) becomes

\[ -\frac{d^2}{\nu} (\omega + i(\omega + m\Omega_1\Omega_l)) (-d^2|k|^2) \frac{2\alpha d\delta}{\nu\Omega_1} u = -k_z^2 d^2 (-4\alpha \Omega_1 d^4/\nu^2)\Omega_l v/(R_1 \Omega_1). \tag{B 4} \]

Simplifying this equation yields

\[ (\omega + i(\omega + m\Omega_1\Omega_l)) |k|^2 u = \nu k_z^2 2\Omega_1 \Omega_l d/ (\delta R_1), \tag{B 5} \]

and, finally,

\[ (\omega + i(\omega + m\Omega_1\Omega_l)) u = 2\alpha^2 \Omega_1 \Omega_l v, \tag{B 6} \]

where \( \alpha = k_z/|k| \). The second equation in (B 1) takes the form

\[ (\omega + i(\omega + m\Omega_1\Omega_l)) v = -2\alpha u \delta R_1 / d, \tag{B 7} \]

and, finally,

\[ (\omega + i(\omega + m\Omega_1\Omega_l)) v = -2\Omega (1 + \text{Ro}) u. \tag{B 8} \]

The equations (B 6) and (B 8) constitute the following system

\[ (\omega + i(\omega + m\Omega_1\Omega_l)) u = 2\alpha^2 \Omega_1 \Omega_l v, \]

\[ (\omega + i(\omega + m\Omega_1\Omega_l)) v = -2\Omega (1 + \text{Ro}) u. \tag{B 9} \]

Since \( \Omega \approx \Omega_1 \Omega_l \), then

\[ (\omega + i(\omega + m\Omega)) u = 2\alpha^2 \Omega v, \]

\[ (\omega + i(\omega + m\Omega)) v = -2\Omega (1 + \text{Ro}) u. \tag{B 10} \]

The system (B 10) can be written in the matrix form \( A \mathbf{w} = i\omega \mathbf{w} \) with the vector \( \mathbf{w} = (u, v)^T \) and

\[ A = \begin{pmatrix} -im\Omega - \omega & 2\alpha^2 \Omega \\ -2\Omega (1 + \text{Ro}) & -im\Omega - \omega \end{pmatrix}. \tag{B 11} \]

The matrix \( A \) is nothing else but the submatrix of the matrix \( H \) defined by Eq. (1.10) situated at the corner corresponding to the first two rows and first two columns of \( H \).

Let \( A_0 = A(\omega = 0) \), then

\[ A_0 = -G^{-1} \overline{A_0}^T G, \quad G = iJ, \quad J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \tag{B 12} \]

meaning that \( F = -iGA_0 = \overline{F}^T \) is a Hermitian matrix:

\[ F = \begin{pmatrix} 2\Omega (1 + \text{Ro}) & im\Omega \\ -im\Omega & 2\alpha^2 \Omega \end{pmatrix}. \tag{B 13} \]
Instabilities in magnetized rotational flows

The next equation gives the coefficients of the dispersion relation (6.6):

\[ F \mathbf{w} = i \omega \mathbf{w}, \quad F = \mathbf{F}^T. \]  

(B.14)

Appendix C. Coefficients of the dimensionless dispersion relations

The coefficients of the complex polynomial (6.3) are:

\[ a_0 = 1, \quad b_0 = 0, \quad a_1 = 2 \left( \sqrt{P_m} + \frac{1}{\sqrt{P_m}} \right), \quad b_1 = 4n\text{Re}\sqrt{P_m}, \]

\[ a_2 = 2(\beta^2\text{Ha}^2 - 3\text{Re}^2P_m)n^2 + 4\beta\text{Ha}^2n \]

\[ + 2(1 + (1 - 2\text{Rb}\beta^2)\text{Ha}^2) + 4\text{Re}^2(1 + \text{Ro})P_m + \frac{\beta^2}{4}, \quad b_2 = 6n\text{Re}(1 + P_m), \]

\[ a_3 = a_1(\beta^2\text{Ha}^2 - 3\text{Re}^2P_m)n^2 + 2a_1\beta\text{Ha}^2n \]

\[ + a_1(1 + (1 - 2\text{Rb}\beta^2)\text{Ha}^2) + 8\text{Re}^2(1 + \text{Ro})\sqrt{P_m}, \]

\[ b_3 = 4n^3\sqrt{P_m}\text{Re}(\beta^2\text{Ha}^2 - \text{Re}^2P_m) \]

\[ + 2n\text{Re}(4P_m^2\text{Re}^2(1 + \text{Ro}) + (1 + P_m)^2 + 2P_m(1 + \text{Ha}^2))/\sqrt{P_m} \]

\[ - 8(1 - n^2 + \beta n(1 + \text{Rb}))\beta\text{Ha}^2\text{Re}\sqrt{P_m}, \]

\[ a_4 = ((\beta^2\text{Ha}^2 - \text{Re}^2P_m)n^2 + 2\text{Ha}^2\beta n + \text{Ha}^2 + 2\text{PmRe}^2)^2 \]

\[ + 2(2\text{Re}^2P_m\text{Ro} + 1)((\text{Ha}^2\beta^2 - \text{Re}^2P_m)n^2 + 2\text{Ha}^2\beta n + \text{Ha}^2) - (1 + P_m)\text{Re}^2n^2 \]

\[ + 4\text{Re}^2(1 + \text{Ro}) - (\text{Ha}^2 + 2\text{PmRe}^2)^2 + \text{Ha}^4 + 1 - 4\text{Rb}\beta\text{Ha}^2 \]

\[ - 4\text{Ha}^2\beta^2(\text{Ha}^2(\beta n + 1)^2 - \text{PmRe}^2n^2)(1 + \text{Rb}), \]

\[ b_4 = 2\text{Re}(1 + P_m)(\beta^2\text{Ha}^2 - \text{Re}^2P_m)n^3 + 4\text{Re}^2\beta(1 + P_m)n^2 \]

\[ + 2\text{Re}(2(1 + \text{Ro})(2\text{Re}^2P_m - \beta^2\text{Ha}^2(1 - P_m)) + (1 + P_m)(1 + \text{Ha}^2(1 - 2\beta^2(1 + \text{Rb}))))n \]

\[ - 4\beta\text{Ha}^2\text{Re}(2 + (1 - P_m)\text{Ro}). \]  

(C.1)

The next equation gives the coefficients of the dispersion relation (6.6):

\[ a_0 = 1, \quad b_0 = 0, \quad a_1 = 2 \left( \frac{2\beta^2}{\text{Rm}} - 3 \right) n^2 + 4\beta\text{N}n \]

\[ + \frac{2}{\text{Rm}} \left( \frac{1}{\text{Re}} + (1 - 2\text{Rb}\beta^2)\text{N} \right) + 4(1 + \text{Ro}) + \frac{\beta^2}{4}, \quad b_2 = \frac{3}{4}a_1b_1, \]

\[ a_3 = a_1 \left( \frac{\beta^2}{\text{Rm}} - 3 \right) n^2 + 2a_1\beta\frac{\text{N}}{\text{Rm}}n + \frac{a_1}{\text{Rm}} \left( \frac{1}{\text{Re}} + (1 - 2\text{Rb}\beta^2)\text{N} \right) + \frac{8}{\text{Rm}}(1 + \text{Ro}), \]

\[ b_3 = 4 \left( \frac{\beta^2}{\text{Rm}} - 1 \right) n^3 + 2n \left( 4(1 + \text{Ro}) + \frac{\beta^2}{4} + \frac{2}{\text{Rm}} (\frac{1}{\text{Re}} + \text{N}) \right) \]

\[ - 8(1 - n^2 + \beta n(1 + \text{Rb})) \frac{2\beta\text{N}}{\text{Rm}} \cdot \]

\[ a_4 = \left( \frac{\beta^2}{\text{Rm}} - 1 \right)^2 n^4 + 4\beta\text{N} \left( \frac{\beta^2}{\text{Rm}} - 1 \right) n^3 \]

\[ + \left( \frac{2}{\text{Rm}} \left( \frac{\beta^2}{\text{Rm}} - 1 \right) \text{N} + \frac{1}{\text{Re}} - 2(\beta^2(1 + \text{Rb})\text{N} - (1 + \text{Ro})\text{Rm}) + \frac{4\beta^2\text{N}}{\text{Rm}^2} - \frac{\beta^2}{4} \right) n^2 \]

\[ + \frac{4\beta\text{N}}{\text{Rm}} \text{N} + \frac{1}{\text{Rm}^2} \left( (\text{N} + \frac{1}{\text{Re}})^2 - 4\frac{\beta^2}{\text{Rm}} \text{N} - (1 + \text{Ro})\text{Rm} \right) n \]

\[ + \frac{1}{\text{Rm}^2} \left( (\text{N} + \frac{1}{\text{Re}})^2 - 4\frac{\beta^2}{\text{Rm}} \text{N} + 4(1 + \text{Ro}) - 4\beta^2(1 + \text{Rb}) \right), \]

\[ b_4 = a_1 \left( \frac{\beta^2}{\text{Rm}} - 1 \right) n^3 + 2a_1\beta\frac{\text{N}}{\text{Rm}}n^2 - \frac{4\beta\text{N}}{\text{Rm}} (\frac{1}{\text{Rm}} + \frac{1}{\text{Re}}) \text{Rm} \]

\[ + \left( \frac{\beta^2}{\text{Rm}} \left( \frac{1}{\text{Re}} + (1 + 2\beta^2(\text{Ro} - \text{Rb}))\text{N} - \frac{8(1 + \text{Ro})}{\text{Rm}} \left( \frac{\beta^2}{\text{Rm}} - 1 \right) \right) \right) n. \]
